Pseudodifferential Calculus and Hadamard states

Christian Gérard

University of Paris Sud

Abstract In this talk we will describe the use of pseudodifferential calculus to construct and study Hadamard states for free Klein-Gordon fields on globally hyperbolic spacetimes.

Pseudodifferential calculus on manifolds is a standard tool of microlocal analysis which actually predates the notion of wavefront set.

We will give a brief description of various pseudodifferential calculi on manifolds and relate the construction of Hadamard states done with Michal Wrochna and Omar Oulghazi with the well-known method of the mode expansion in the case of cosmological spacetimes.

We will also give a new proof of the Hadamard property of the Hartle-Hawking-Israel state for static bifircate Killing horizons due to Sanders.
