A GORENSTEIN CRITERION FOR STRONGLY $F$-REGULAR AND LOG TERMINAL SINGULARITIES

ANURAG K. SINGH, SHUNSUKE TAKAGI, AND MATTEO VARBARO

Dedicated to Professor Craig Huneke on the occasion of his sixty-fifth birthday.

Abstract. A conjecture of Hirose, Watanabe, and Yoshida offers a characterization of when a standard graded strongly $F$-regular ring is Gorenstein, in terms of an $F$-pure threshold. We prove this conjecture under the additional hypothesis that the anti-canonical cover of the ring is Noetherian. Moreover, under this hypothesis on the anti-canonical cover, we give a similar criterion for when a normal $F$-pure (resp. log canonical) singularity is quasi-Gorenstein, in terms of an $F$-pure (resp. log canonical) threshold.

1. Introduction

Let $R$ be an $F$-pure domain of positive characteristic, and $a$ a nonzero proper ideal. The $F$-pure threshold $\text{fpt}(a)$ was defined by Watanabe and the second author of this paper [36]; it may be viewed as a positive characteristic analogue of the log canonical threshold, and is an important measure of the singularities of the pair $(\text{Spec } R, V(a))$. For example, a local ring $(R, \mathfrak{m})$ is regular if and only if $\text{fpt}(\mathfrak{m}) > \dim R - 1$.

We say that $R$ is strongly $F$-regular if $\text{fpt}(a) > 0$ for each nonzero proper ideal $a$ of $R$. It is well-known that each strongly $F$-regular ring is Cohen-Macaulay and normal; it is then natural to ask: when is a strongly $F$-regular ring Gorenstein? Toward answering this in the graded context, Hirose, Watanabe, and Yoshida proposed the following:

Conjecture 1.1 ([19, Conjecture 1.1 (2)]). Let $R$ be a standard graded strongly $F$-regular ring, with $R_0$ an $F$-finite field of characteristic $p > 0$. Let $\mathfrak{m}$ be the unique homogeneous maximal ideal of $R$. Then $\text{fpt}(\mathfrak{m}) = -\alpha(R)$ if and only if $R$ is Gorenstein.

We prove that the conjecture holds for many classes of (not necessarily strongly $F$-regular) $F$-pure normal standard graded rings:

Theorem A (Corollaries 3.17, 4.12). Let $R$ be an $F$-pure, normal, standard graded ring, with $R_0 = k$ an $F$-finite field of characteristic $p > 0$. Let $\mathfrak{m}$ denote the homogeneous maximal ideal of $R$. Set $X = \text{Spec } R$, and suppose that the anti-canonical cover $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ of $X$ is a Noetherian ring. Then $\text{fpt}(\mathfrak{m}) = -\alpha(R)$ if and only if $R$ is quasi-Gorenstein.

Note that a ring is Gorenstein if and only if it is Cohen-Macaulay and quasi-Gorenstein. Under the hypotheses of Theorem A, the anti-canonical cover $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is known to be Noetherian in each of the following cases:

(i) $R$ is $\mathbb{Q}$-Gorenstein,
(ii) $R$ is a semigroup ring,
(iii) $R$ is a determinantal ring,
(iv) $R$ is a strongly $F$-regular ring of dimension at most three,
(v) $R$ is a four-dimensional strongly $F$-regular ring, of characteristic $p > 5$.

We give two proofs of Theorem A: the first has the advantage that it can be adapted to obtain results in the local setting, e.g., Theorem 3.14. The second proof, while limited to the graded context, provides a technique for computing the numerical invariants at hand; see Proposition 4.3 for the case of determinantal rings. We describe the two techniques, after recalling some definitions:

Let $k$ be an $F$-finite field, that is, a field of characteristic $p > 0$ such that $[k : k^p] < \infty$, and let $R$ be an integral domain essentially of finite type over $k$. Suppose that $R$ is $F$-pure, i.e., the $e$-th iterated Frobenius map $F^e : R \rightarrow F^e_R$ with $x \mapsto F^e(x^p)$ splits as an $R$-linear map for each $e \geq 1$. Given a nonzero ideal $a \subseteq R$, and integer $e \geq 1$, set $\nu_e(a)$ to be the largest integer $r \geq 0$ such that there exists a nonzero element $c$ in $a^r$ for which the composite map

$$R \xrightarrow{F^e} F^e_R \xrightarrow{F^e c} F^e_R, \quad x \mapsto F^e(x^p) \mapsto F^e(cx^p),$$

splits as an $R$-module homomorphism. Then, $\text{fpt}(a)$ is defined to be $\lim_{e \rightarrow \infty} \nu_e(a)/p^e$.

The first proof of Theorem A uses an invariant $c(a)$ that was originally introduced in [31]; Given a nonzero ideal $a \subseteq R$, this invariant is defined in terms of the Grothendieck trace of the iterated Frobenius map $\text{Tr}^e : F^e_*\omega_R \rightarrow \omega_R$, where $\omega_R$ is the canonical module of $R$. For an $F$-pure normal graded ring $(R, \mathfrak{m})$, one has

$$\text{fpt}(\mathfrak{m}) \leq c(\mathfrak{m}) \leq -a(R),$$

with equality holding when $R$ is a quasi-Gorenstein standard graded ring; see Propositions 3.5 and 3.6. Thus, it suffices to show that if $\text{fpt}(\mathfrak{m}) = c(\mathfrak{m})$, then $R$ is quasi-Gorenstein. Generalizing the argument of [36, Theorem 2.7], we are indeed able to prove this when the anti-canonical cover of $R$ is Noetherian. We also use the invariant $c(\mathfrak{m})$ in answering another question of Hirose, Watanabe, and Yoshida, [19, Question 6.7]; see Corollary 3.18.

Our second proof uses the so-called Federer-type criterion: Writing the standard graded ring $R$ as $S/I$, for $S$ a polynomial ring and $I$ a homogeneous ideal, we characterize $\nu_e(\mathfrak{m})$ in terms of the ideal $I^{[p^e]} : S I$, and use this to show that $-\nu_e(\mathfrak{m})$ equals the degree of a minimal generator of the $(1 - p^e)$-th symbolic power of $\omega_R$, see Theorem 4.1. Using this, we give explicit computations of $\text{fpt}(\mathfrak{m})$ in many situations, e.g., for determinant rings and for $\mathbb{Q}$-Gorenstein rings, see Propositions 4.3 and 4.5. We also prove that if $(R, \mathfrak{m})$ is a $\mathbb{Q}$-Gorenstein normal domain, with index coprime to $p$, then the pair $(R, \mathfrak{m}^{\text{fpt}(\mathfrak{m})})$ is sharply $F$-pure, Proposition 4.13.

Thus far we have discussed singularities in positive characteristic; we also prove analogous result in characteristic zero. de Fernex-Hacon [10] extended the definition of log terminal and log canonical singularities to the non-$\mathbb{Q}$-Gorenstein setting, which can be regarded as the characteristic zero counterparts of strongly $F$-regular and $F$-pure rings. Using their definition, we formulate a characteristic zero analogue of Theorem A as follows:

**Theorem B** (Corollary 5.13). Let $R$ be a standard graded normal ring, with $R_0$ an algebraically closed field of characteristic zero. Set $\mathfrak{m}$ to be the homogeneous maximal ideal of $R$. Assume that $X := \text{Spec} R$ has log canonical singularities in the sense of de Fernex-Hacon; set

$$\text{lct}(\mathfrak{m}) = \sup\{t \geq 0 \mid (X, \mathfrak{m}^t) \text{ is log canonical in the sense of de Fernex-Hacon}\}.$$

(1) Then $\text{lct}(\mathfrak{m}) \leq -a(R)$. 

(2) Suppose, in addition, that the anti-canonical cover \( \bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X) \) is Noetherian. Then \( \operatorname{lct}(m) = -a(R) \) if and only if \( R \) is quasi-Gorenstein.

We remark that in the situation of Theorem B, the anti-canonical cover is Noetherian whenever \( X \) has log terminal singularities in the sense of de Fernex-Hacon, or if \( R \) is Q-Gorenstein. Thus, Theorem B gives an affirmative answer to a conjecture of De Stefani-Núñez-Betancourt [11, Conjecture 6.9].

In order to prove Theorem B, we introduce a new invariant \( d(a) \) for an ideal \( a \) of a normal variety \( X \) with Du Bois singularities, in terms of a variant of multiplier modules, see Definition 5.4. We are then able to employ the same strategy as in the first proof of Theorem A, using \( d(a) \) in place of \( c(a) \).

Throughout this paper, all rings are assumed to be Noetherian (except possibly for anti-canonical covers), commutative, with unity. By a standard graded ring, we mean an \( \mathbb{N} \)-graded ring \( R = \bigoplus_{n \geq 0} R_n \), with \( R_0 \) a field, such that \( R \) is generated as an \( R_0 \)-algebra by finitely many elements of \( R_1 \).

2. Preliminaries on \( F \)-singularities

In this section, we briefly review the theory of \( F \)-singularities. In order to state the definitions, we first introduce the following notation:

Let \( R \) be a ring of prime characteristic \( p > 0 \). We denote by \( R^\circ \) the set of elements of \( R \) that are not in any minimal prime ideal. Given an \( R \)-module \( M \) and \( e \in \mathbb{N} \), the \( R \)-module \( F_e^* M \) is defined by the following two conditions: (i) \( F_e^* M = M \) as an abelian group, and (ii) the \( R \)-module structure of \( F_e^* M \) is given by \( r \cdot x := r^{pe} x \) for \( r \in R \) and \( x \in F_e^* M \). We write elements of \( F_e^* M \) in the form \( F_e^* x \) with \( x \in M \). The \( e \)-th iterated Frobenius map is the \( R \)-linear map \( F_e : R \to F_e^* R \) sending \( x \) to \( F_e^* x \). We say that \( R \) is \( F \)-finite if the Frobenius map is finite, that is, \( F_e^1 R \) is a finitely generated \( R \)-module. When \( (R, m) \) is local, the \( e \)-th iterated Frobenius map \( F_e : R \to F_e^* R \) induces a map \( F_e^e : H^i_m(R) \to H^i_m(R) \) for each \( i \).

We recall the definition of classical \( F \)-singularities:

**Definition 2.1.** Let \( R \) be an \( F \)-finite reduced ring of prime characteristic \( p > 0 \).

(i) We say that \( R \) is \( F \)-pure if the Frobenius map \( R \to F_e^* R \) splits as an \( R \)-linear map.

(ii) We say that \( R \) is strongly \( F \)-regular if for every \( c \in R^\circ \), there exists a power \( q = pe \) of \( p \) such that the \( R \)-linear map \( R \to F_e^* R \) sending \( 1 \) to \( F_e^e c \) splits.

(iii) When \( (R, m) \) is local, we say that \( R \) is \( F \)-injective if \( F_e^e : H^i_m(R) \to H^i_m(R) \) is injective for each \( i \). In general, we say that \( R \) is \( F \)-injective if the localization \( R_m \) is \( F \)-injective for each maximal ideal \( m \) of \( R \).

(iv) When \( (R, m) \) is local, we say that \( R \) is \( F \)-rational if \( R \) is Cohen-Macaulay and if for every \( c \in R^\circ \), there exists \( e \in \mathbb{N} \) such that \( c F_e^e : H^d_m(R) \to H^d_m(R) \) sending \( z \) to \( c F_e^e(z) \) is injective. In general, we say that \( R \) is \( F \)-rational if the localization \( R_m \) is \( F \)-rational for each maximal ideal \( m \) of \( R \).

Next we generalize these to the pair setting, see [29, 36]:

**Definition 2.2.** Let \( a \) be an ideal of an \( F \)-finite reduced ring \( R \) of prime characteristic \( p \) such that \( a \cap R^\circ \neq \emptyset \).

(i) For a real number \( t \geq 0 \), the pair \( (R, a^t) \) is sharply \( F \)-pure if there exist \( q = pe \) and \( c \in a^{t(q-1)} \) such that the \( R \)-linear map \( R \to F_e^* R \) sending \( 1 \) to \( F_e^e c \) splits. The pair \( (R, a^t) \) is weakly \( F \)-pure if there exist infinitely many \( e \in \mathbb{N} \) and associated elements \( c_e \in a^{t(p^e-1)} \) such that each \( R \)-linear map \( R \to F_e^* R \) sending \( 1 \) to \( F_e^e c_e \) splits.
(ii) Suppose that $R$ is $F$-pure. Then the $F$-pure threshold $fpt(a)$ of $a$ is defined as
\[ fpt(a) = \sup \{ t \in \mathbb{R}_{\geq 0} \mid (R, a^t) \text{ is weakly } F\text{-pure} \}. \]

(iii) Suppose that $R$ is a normal domain and $\Delta$ is an effective $\mathbb{Q}$-divisor on $X := \text{Spec } R$. For a real number $t \geq 0$, the pair $((R, \Delta); a^t)$ is sharply $F$-pure if there exists $q = p^e$ and $c \in a^{(q-1)}$ such that the $R$-linear map
\[ R \rightarrow F^e_* \mathcal{O}_X(|(q-1)\Delta|) \quad \text{with} \quad 1 \mapsto F^e_* c \]
splits. The pair $(R, a^t)$ is weakly $F$-pure if there exist infinitely many $e \in \mathbb{N}$ and associated elements $c_e \in a^{(tp^{e-1})}$ such that each $R$-linear map
\[ R \rightarrow F^e_* \mathcal{O}_X(|(p^e-1)\Delta|) \quad \text{with} \quad 1 \mapsto F^e_* c_e. \]
splits. If $(R, \Delta)$ is weakly $F$-pure, then the $F$-pure threshold $fpt(\Delta; a)$ of $a$ with respect to the pair $(R, \Delta)$ is defined by
\[ fpt(\Delta; a) = \sup \{ t \in \mathbb{R}_{\geq 0} \mid ((R, \Delta); a^t) \text{ is weakly } F\text{-pure} \}. \]

Remark 2.3. Sharp $F$-purity implies weak $F$-purity. When $a = R$, the sharp $F$-purity and the weak $F$-purity of $(R, a^t)$ are equivalent to the $F$-purity of $R$. Suppose that $R$ is $F$-pure. It is easy to check that if $(R, a^t)$ is weakly $F$-pure with $t > 0$, then $(R, a^{t+\varepsilon})$ is sharply $F$-pure for every $t \geq \varepsilon > 0$ (cf. [29, Lemma 5.2]). Thus,
\[ fpt(a) = \sup \{ t \in \mathbb{R}_{\geq 0} \mid (R, a^t) \text{ is sharply } F\text{-pure} \}. \]

The following is a standard application of Matlis duality, which we will use in Section 3.

Lemma 2.4 (cf. [16, Proposition 2.4]). Let $(R, \mathfrak{m})$ be a $d$-dimensional $F$-finite normal local ring of characteristic $p > 0$, $\Delta$ be an effective $\mathbb{Q}$-divisor on $X = \text{Spec } R$ and $a$ a nonzero ideal of $R$. For any real number $t \geq 0$, the pair $((R, \Delta); a^t)$ is weakly $F$-pure if and only if there exist infinitely many $e \in \mathbb{N}$ and associated elements $c_e \in a^{(tp^{e-1})}$ such that
\[ c_e F^e_{X,\Delta}; H^d_m(\omega_X) \xrightarrow{F^e_{X,\Delta}} H^d_m(\mathcal{O}_X(|p^eK_X + (p^e-1)\Delta|)) \xrightarrow{x \cdot c_e} H^d_m(\mathcal{O}_X(|p^eK_X + (p^e-1)\Delta|)) \]
is injective, where $F^e_{X,\Delta}$ is the map induced by the $R$-linear map $R \rightarrow F^e_* \mathcal{O}_X(|(p^e-1)\Delta|)$ sending 1 to $F^e_* 1$. $\quad \square$

The following is a reformulation of the so-called “Fedder-type criterion,” that we will use in Section 4.

Proposition 2.5. Let $S = k[x_1, \ldots, x_n]$ be a polynomial ring over an $F$-finite field $k$ of characteristic $p > 0$ and $I$ be a homogeneous ideal of $S$. Suppose that $R := S/I$ is $F$-pure. Given an $e \in \mathbb{N}$ and a homogeneous ideal $a \subset S$ containing $I$ such that $aR \cap R^e \neq \emptyset$, we define the integer $\nu_e(a)$ by
\[ \nu_e(a) := \max \{ r \geq 0 \mid a^r(I^{[p^e]} : I) \subsetneq (x_1^{p^e}, \ldots, x_n^{p^e}) \}. \]

(1) The pair $(R, (aR)^t)$ is sharply (resp. weakly) $F$-pure if and only if $\nu_e(a) \geq [(p^e-1)t]$ for some $e$ (resp. $\nu_e(a) \geq [(p^e-1)t]$ for infinitely many $e$).

(2) $fpt(aR) = \lim_{e \to \infty} \nu_e(a)/p^e$.

Proof. It follows from [35, Lemma 3.9] (where the criterion for $F$-purity is stated in the local setting, but the same criterion holds in the graded setting). $\square$

In order to generalize the definition of $F$-rational and $F$-injective rings to the pair setting, we use the notion of $a^t$-tight closure and $a^t$-sharp Frobenius closure.
Definition 2.6. Let $a$ be an ideal of a reduced ring $R$ of prime characteristic $p > 0$ such that $a \cap R^e \neq \emptyset$.

(i) ([17, Definition 6.1]) For an ideal $I \subseteq R$, the $a^t$-tight closure $I^{a^t}$ of $I$ is defined to be the ideal of $R$ consisting of all elements $x \in R$ for which there exists $c \in R^e$ such that $ca^{[(q-1)t]}x^q \subseteq I[q]$ for all large $q = p^e$.

(ii) ([29, Definition 3.10]) For an ideal $I \subseteq R$, the $a^t$-sharp Frobenius closure $I^{F_a^t}$ of $I$ is defined to be the ideal of $R$ consisting of all elements $x \in R$ such that $a^{[(q-1)t]}x^q \subseteq I[q]$ for all large $q = p^e$.

(iii) Suppose that $(R, \mathfrak{m})$ is local. The $a^t$-sharp Frobenius closure $0^{F_a^t}_{H^{(R)}_{\mathfrak{m}}}$ of the zero submodule in $H^{(R)}_{\mathfrak{m}}(R)$ is defined to be the submodule of $H^{(R)}_{\mathfrak{m}}(R)$ consisting of all elements $z \in H^{(R)}_{\mathfrak{m}}(R)$ such that $a^{[(q-1)t]}F^{e}_{H^{(R)}_{\mathfrak{m}}}(z) = 0$ in $H^{(R)}_{\mathfrak{m}}(R)$ for all large $q = p^e$.

Remark 2.7. Let $(R, \mathfrak{m})$ be an $F$-finite reduced local ring of characteristic $p > 0$. Let $\text{Tr}^e : F^*_s \omega_R \rightarrow \omega_R$ be the $e$-th iteration of the trace map on $R$, that is, the $\omega_R$-dual of the $e$-th iterated Frobenius map $F^e : R \rightarrow F^e R$. It then follows from an argument similar to the proof of [15, Lemma 2.1] that $0^{F_a^t}_{H^{(R)}_{\mathfrak{m}}(R)} = 0$ if and only if

$$\sum_{e \geq e_0} \text{Tr}^e(F^e_s(a^{[(p^e-1)t]}) \omega_R)) = \omega_R$$

for every integer $e_0 \geq 0$.

Definition 2.8. Let $R$ be an $F$-finite Cohen-Macaulay reduced ring of prime characteristic $p > 0$, $a$ be an ideal of $R$ such that $a \cap R^e \neq \emptyset$, and $t \geq 0$ be a real number.

(i) ([31, Definition 6.1]) When $R$ is local, $(R, a^t)$ is said to be $F$-rational if $J^{a^t} = J$ for every ideal $J$ generated by a full system of parameters for $R$.

(ii) When $R$ is local, $(R, a^t)$ is said to be sharply $F$-injective if $J^{F_a^t} = J$ for every ideal $J$ generated by a full system of parameters for $R$.

When $R$ is not local, the pair $(R, a^t)$ is said to be $F$-rational (resp. sharply $F$-injective) if the localization $(R_{\mathfrak{m}}, a^t_{\mathfrak{m}})$ at $\mathfrak{m}$ is $F$-rational (resp. sharply $F$-injective) for every maximal ideal $\mathfrak{m}$ of $R$. When $a = R$, this definition coincides with the one in Definition 2.1.

We review basic properties of sharply $F$-injective pairs and $F$-rational pairs.

Lemma 2.9. Let $R$ be an $F$-finite reduced ring of prime characteristic $p > 0$, $a$ be an ideal of $R$ such that $a \cap R^e \neq \emptyset$, and $t \geq 0$ be a real number. Set $d := \dim R$.

(1) Suppose that $(R, \mathfrak{m})$ is Cohen-Macaulay. Then the following are equivalent:

(a) $(R, a^t)$ is sharply $F$-injective (resp. $F$-rational).

(b) $J^{F_a^t} = J$ (resp. $J^{a^t} = J$) for an ideal $J$ generated by a full system of parameters.

(c) $0^{F_a^t}_{H^{(R)}_{\mathfrak{m}}(R)} = 0$ (resp. $0^{a^t}_{H^{(R)}_{\mathfrak{m}}(R)} = 0$).

(2) Suppose that $R$ is $F$-rational.

(a) There exists a rational number $t_0 > 0$ such that $(R, a^{t_0})$ is sharply $F$-injective.

(b) If $(R, a^t)$ is sharply $F$-injective with $t > 0$, then $(R, a^{t-\varepsilon})$ is $F$-rational for every $t \geq \varepsilon > 0$.

(3) Suppose that $(R, \mathfrak{m})$ is local. If $(R, a^t)$ is sharply $F$-pure, then $0^{F_a^t}_{H^{(R)}_{\mathfrak{m}}(R)} = 0$ for every $i$.

When $R$ is quasi-Gorenstein, $(R, a^t)$ is sharply $F$-pure if and only if $0^{F_a^t}_{H^{(R)}_{\mathfrak{m}}(R)} = 0$. 
(4) Let \((R, \mathfrak{m}) \hookrightarrow (S, \mathfrak{n})\) be a flat local homomorphism of \(F\)-finite reduced local rings of characteristic \(p > 0\). Suppose that \(S/\mathfrak{m}S\) is a field which is a separable algebraic extension of \(R/\mathfrak{m}\). Then \(0^{F^{2e}_*}_R H^a_{\mathfrak{m}}(R) = 0\) if and only if \(0^{F^{2e}_*(S)}_S H^a_{\mathfrak{n}}(S) = 0\).

**Proof.** We may assume throughout that \((R, \mathfrak{m})\) is local. Let \(J\) be an ideal generated by a full system of parameters for \(R\).

(1) The \(F\)-rational case follows from [31, Lemma 6.3] and the sharp \(F\)-injective case follows from an analogous argument.

(2) First we will show (a). Fix a nonzero element \(f \in \mathfrak{a}\). Since \(R\) is \(F\)-rational, there exists \(e_0 \in \mathbb{N}\) such that \(f^{F^e}_{H^a_{\mathfrak{m}}(R)} : H^a_{\mathfrak{m}}(R) \rightarrow H^a_{\mathfrak{m}}(R)\) is injective. Then for each \(n \in \mathbb{N}\), the map

\[
\bigoplus_{i=0}^{e} F^{e}_{H^a_{\mathfrak{m}}(R)} : H^a_{\mathfrak{m}}(R) \rightarrow H^a_{\mathfrak{m}}(R)
\]

is also injective. Set \(t_0 = 1/(p^{e_0} - 1)\) and let \(z \in 0^{F^{2e}_*}_{R} H^a_{\mathfrak{m}}(R)\). Since

\[
f^{1+p^{e_0}+\ldots+p^{(n-1)e_0}}_{H^a_{\mathfrak{m}}(R)}(z) = 0\]

for sufficiently large \(n\), one has \(z = 0\) by the injectivity of \(f^{1+p^{e_0}+\ldots+p^{(n-1)e_0}}_{H^a_{\mathfrak{m}}(R)}\). It follows that \(0^{F^{2e}_*}_{R} H^a_{\mathfrak{m}}(R) = 0\).

Next we will show (b). Let \(x \in J^{sa^{1-t}}\). Since \(1\) is a parameter \(a^{1-t}\)-test element by [31, Lemma 6.8] (see [31, Definition 6.6] for the definition of parameter \(a^{1-t}\)-test elements), \(a^{[(q-1)]}x \subseteq a^{[(t-q)]}x \subseteq J^{[q]}\) for all sufficiently large \(q = p^e\). Then the sharp \(F\)-injectivity of \((R, \mathfrak{a}^t)\) implies that \(x \in J\), that is, \(J^{sa^{1-t}} = J\).

(3) Let \(z \in 0^{F^{2e}_*}_{H^a_{\mathfrak{m}}(R)}\). Since \((R, \mathfrak{a}^t)\) is sharply \(F\)-pure, there exist a sufficiently large \(q = p^e\) and \(c \in a^{[(t^e-q^e)-1]}\) such that the \(R\)-linear map \(R \rightarrow F^e_* R\) sending \(1\) to \(F^e_* c\) splits, and in particular, \(c^{F^e}_{H^a_{\mathfrak{m}}(R)} : H^a_{\mathfrak{m}}(R) \rightarrow H^a_{\mathfrak{m}}(R)\) is injective. Then \(z\) has to be zero, because \(c^{F^e}_{H^a_{\mathfrak{m}}(R)}(z) = 0\). That is, \(0^{F^{2e}_*}_{H^a_{\mathfrak{m}}(R)} = 0\).

For the latter assertion, suppose that \(R\) is quasi-Gorenstein. Then by [29, Theorem 4.1], \((R, \mathfrak{a}^t)\) is sharply \(F\)-pure if and only if for infinitely many \(q = p^e\), there exists \(e \in a^{[(t-q^e)-1]}\) such that \(c^{F^e}_{H^a_{\mathfrak{m}}(R)} : H^a_{\mathfrak{m}}(R) \rightarrow H^a_{\mathfrak{m}}(R)\) is injective. Looking at the socle of \(H^a_{\mathfrak{m}}(R)\), we see that this condition is equivalent to saying that \(0^{F^{2e}_*}_{H^a_{\mathfrak{m}}(R)} = 0\).

(4) Since \(H^a_{\mathfrak{m}}(S)\) does not change by passing to the completion of \(S\), we may assume that \(S\) is complete. Let \(T^e_R : F^e_* \omega_R \rightarrow \omega_R\) (resp. \(T^e_S : F^e_* \omega_S \rightarrow \omega_S\)) denote the \(e\)-th iteration of the trace map on \(R\) (resp. \(S\)). It then follows from the proof of [34, Lemma 1.5 (2)] that \(T^e_R \otimes_R S : F^e_* \omega_R \otimes_R S \rightarrow \omega_R \otimes_R S\) is isomorphic to \(T^e_S\) for each \(e \in \mathbb{N}\). By Remark 2.7, \(0^{F^{2e}_*}_{H^a_{\mathfrak{m}}(R)} = 0\) if and only if

\[
\bigoplus_{e \geq e_0} T^e_R : \bigoplus_{e \geq e_0} F^e_* (a^{[(t^e-q^e)-1]} \omega_R) \rightarrow \omega_R
\]

is surjective for every integer \(e_0 \geq 0\). Tensoring with \(S\), we see that this condition is equivalent to the surjectivity of

\[
\bigoplus_{e \geq 0} T^e_S : \bigoplus_{e \geq e_0} F^e_* (a^{[(t^e-q^e)-1]} \omega_S) \rightarrow \omega_S
\]

for every \(e_0 \geq 0\), which holds by Remark 2.7 again if and only if \(0^{F^{2e}_*(aS)}_{H^a_{\mathfrak{n}}(S)} = 0\). \(\square\)
3. Positive characteristic case I

We introduce a new invariant of singularities in positive characteristic, and study its basic properties. Using this, we give a partial answer to Conjecture 1.1.

**Definition 3.1.** Let \((R, \mathfrak{m})\) be a \(d\)-dimensional \(F\)-finite \(F\)-injective local ring of characteristic \(p > 0\), \(\mathfrak{a}\) be an ideal of \(R\) such that \(\mathfrak{a} \cap R^0 \neq \emptyset\), and \(t \geq 0\) be a real number. For each integer \(i\), the threshold \(c_i(\mathfrak{a})\) is defined by

\[
c_i(\mathfrak{a}) = \sup\{t \in \mathbb{R}_\geq 0 \mid 0_{H^i_{\mathfrak{m}}(R)}^{F^{2t} \mathfrak{a}^t} = 0\}.
\]

Note that \(c_i(\mathfrak{a}) = \infty\) when \(H^i_{\mathfrak{m}}(R) = 0\). Also, we simply denote \(c_d(\mathfrak{a})\) by \(c(\mathfrak{a})\).

**Remark 3.2.** Let \(R\) be an \(\mathbb{N}\)-graded ring with \(R_0\) an \(F\)-finite field of characteristic \(p > 0\), and \(\mathfrak{m}\) the homogeneous maximal ideal of \(R\). Then we can define \(c_i(\mathfrak{m})\) similarly, that is,

\[
c_i(\mathfrak{m}) = \sup\{t \in \mathbb{R}_\geq 0 \mid 0_{H^i_{\mathfrak{m}}(R)}^{F^{2t} \mathfrak{m}^t} = 0\}.
\]

Since \(H^i_{\mathfrak{m}}(R) \cong H^i_{\mathfrak{m}R_{\mathfrak{m}}}(R_{\mathfrak{m}})\), we have the equality \(c_i(\mathfrak{m}) = c_i(\mathfrak{m}R_{\mathfrak{m}})\).

**Lemma 3.3.** Let the notation be the same as in Definition 3.1.

1. If \(R\) is Cohen-Macaulay, then \(c(\mathfrak{a}) = \sup\{t \in \mathbb{R}_\geq 0 \mid (R, \mathfrak{a}^t)\) is sharply \(F\)-injective\}.

2. If \(R\) is \(F\)-rational, then \(c(\mathfrak{a}) = \sup\{t \in \mathbb{R}_\geq 0 \mid (R, \mathfrak{a}^t)\) is \(F\)-rational\}.

3. Suppose that \(R\) is \(F\)-pure. Then \(c_i(\mathfrak{a}) \geq \trt(\mathfrak{a}^t)\) for each \(i\). In addition, if \(R\) is quasi-Gorenstein, then \(c(\mathfrak{a}) = \trt(\mathfrak{a})\).

4. \(c(\mathfrak{a})\) is less than or equal to the height \(ht\) of \(\mathfrak{a}\).

5. Suppose that \(R\) is Cohen-Macaulay and the residue field \(R/\mathfrak{m}\) is infinite. If \(J \subset R\) is a minimal reduction of \(\mathfrak{m}\), then \(\mathfrak{m}^{d+1-[c(\mathfrak{m})]} \subseteq J\).

6. Suppose that \(R\) is Cohen-Macaulay. If \(c(\mathfrak{m}) > d - 1\), then \(R\) is regular and in particular \(c(\mathfrak{m}) = d\).

**Proof.** (1) (resp. (2), (3)) follows from Lemma 2.9 (1) (resp. (2), (3)).

(4) Since the trace map commutes with localization, by Remark 2.7, \(c(\mathfrak{a}) \leq c(\mathfrak{a} \mathfrak{p})\) for every prime ideal \(\mathfrak{p}\) containing \(\mathfrak{a}\). Localizing at a minimal prime of \(\mathfrak{a}\), we may assume that \(ht\mathfrak{a} = d\). We can also assume by Lemma 2.9 (4) that the residue field \(R/\mathfrak{m}\) is infinite. Let \(J\) be a minimal reduction of \(\mathfrak{a}\), and we will show that \(0^{F^{2t} \mathfrak{a}^t}_{H^i_{\mathfrak{m}}(R)} \supseteq (0 : J)_{H^i_{\mathfrak{m}}(R)} \neq 0\) for every \(t > d\). Let \(z \in (0 : J)_{H^i_{\mathfrak{m}}(R)}\). Note that if \(t > d\), then \(J^{[q]} \supseteq \mathfrak{a}^{[t(q-1)]}\) for all large \(q = p^e\). Then

\[
a^{[t(q-1)]}F^e_{H^i_{\mathfrak{m}}(R)}(z) \subseteq J^{[q]}F^e_{H^i_{\mathfrak{m}}(R)}(z) = F^e_{H^i_{\mathfrak{m}}}(Jz) = 0
\]

for such \(q = p^e\), which implies that \(z \in 0^{F^{2t} \mathfrak{a}^t}_{H^i_{\mathfrak{m}}(R)}\).

(5) It follows from Remark 2.7 that \(\sum_{e \geq e_0} \text{Tr}^e(F^e_\mathfrak{m}(\mathfrak{m}^{[c(\mathfrak{m})-\varepsilon(p^e-1)] \omega_R}) = \omega_R\) for all \(e_0 \in \mathbb{Z}_{\geq 0}\) and for all \(c(\mathfrak{m}) \geq \varepsilon > 0\) (when \(c(\mathfrak{m}) = 0\), we put \(\varepsilon = 0\)). Multiplying by \(\mathfrak{m}^{d+1-[c(\mathfrak{m})]}\) on
both sides, one has
\[
\begin{align*}
\mathfrak{m}^{d+1-\lfloor c(m) \rfloor} \omega_R &= \mathfrak{m}^{d+1-\lfloor c(m) \rfloor} \sum_{e \geq e_0} \text{Tr}^e \left( F^e_s(\mathfrak{m}^{\lfloor c(m) - \varepsilon \rfloor_-(p^e - 1)} \omega_R) \right) \\
&= \sum_{e \geq e_0} \text{Tr}^e \left( F^e_s(\mathfrak{m}^{\lfloor c(m) - \varepsilon \rfloor_-(p^e - 1)} + (d+1-\lfloor c(m) \rfloor)p^e \omega_R) \right) \\
&\subseteq \sum_{e \geq e_0} \text{Tr}^e \left( F^e_s(\mathfrak{m}^{d_0 \varepsilon} \omega_R) \right) \\
&\subseteq \sum_{e \geq e_0} \text{Tr}^e \left( F^e_s(J_{\varepsilon} \omega_R) \right) \\
&\subseteq J_{\omega_R}
\end{align*}
\]
for sufficiently large \(e_0\) and for sufficiently small \(\varepsilon > 0\). Since \(R/J\) is the Matlis dual of \(\omega_R/J_{\omega_R}\), this means that \(\mathfrak{m}^{d+1-\lfloor c(m) \rfloor} \subseteq J\).

(6) Let \(J\) be a minimal reduction of \(\mathfrak{m}\); we may assume by Lemma 2.9 (4) that the residue field \(R/\mathfrak{m}\) is infinite. It then follows from (5) that \(\mathfrak{m} = J\), which means that \(\mathfrak{m}\) is generated by at most \(d\) elements, that is, \(R\) is regular. If \(R\) is regular, then \(c(m) = \text{fpt}(m) = d\) by (3) and [36, Theorem 2.7 (1)].

**Example 3.4.** Let \(S\) be the \(n\)-dimensional polynomial ring \(k[x_1, \ldots, x_n]\) over an \(F\)-finite field \(k\). Let \(R = S^{(r)}\) be the \(r\)-th Veronese subring of \(S\) and \(\mathfrak{m}_R\) be the homogeneous maximal ideal of \(R\). Then \(\text{fpt}(\mathfrak{m}_R) = n/r\) and \(c(\mathfrak{m}_R) = \lceil n/r \rceil\).

When \(R\) is an \(\mathbb{N}\)-graded ring, the \(i\)-th \(a\)-invariant \(a_i(R)\) is defined by
\[
a_i(R) = \max\{n \in \mathbb{Z} \mid [H^n_m(R)]_n \neq 0\}
\]
for each \(i\). The following proposition can be viewed as an extension of [11, Theorem 4.3].

**Proposition 3.5.** Let \(R\) be an \(F\)-injective \(\mathbb{N}\)-graded ring, with \(R_0 = k\) an \(F\)-finite field of characteristic \(p > 0\). Let \(\mathfrak{m}\) be the homogeneous maximal ideal of \(R\). Then \(c_i(\mathfrak{m}) \leq -a_i(R)\) for each \(i\). In particular, if \(R\) is \(F\)-pure, then by Lemma 3.3 (3), one has the inequality \(\text{fpt}(\mathfrak{m}) \leq -a_i(R)\) for every integer \(i\).

**Proof.** We may assume that \(H^i_m(R) \neq 0\). We will then show that \(c_i(\mathfrak{m}) \leq -a_i(R) + \varepsilon\), that is, \(0^{\hat{F}^{\mathfrak{m}}_{H^i_m(R)}} \neq 0\), for every \(\varepsilon > 0\). Note that \(a_i(R) \leq 0\), because \(R\) is \(F\)-injective. Let \(z \in [H^i_m(R)]_{a_i(R)}\) be a nonzero element. Since \([(-a_i(R) + \varepsilon)(q - 1)] + a_i(R)q > 0\) for all sufficiently large \(q = p^e\), one has
\[
\mathfrak{m}^{[-a_i(R)+\varepsilon(q-1)]} F^e_{H^i_m(R)}(z) \subseteq [H^i_m(R)]_{q > 0} = 0
\]
for such \(q\), which means that \(z \in 0^{\hat{F}^{\mathfrak{m}}_{H^i_m(R)}}_{H^i_m(R)}\). \(\Box\)

We record two cases in which the above result can be strengthened to an equality:

**Proposition 3.6.** Let \(R\) be an \(F\)-injective standard graded ring with \(R_0 = k\) an \(F\)-finite field of characteristic \(p > 0\). Let \(\mathfrak{m}\) denote the homogeneous maximal ideal of \(R\). Suppose that one of the following conditions is satisfied:

(1) \(R\) is Cohen-Macaulay,
(2) \(R\) is normal and quasi-Gorenstein.

Then \(c(\mathfrak{m}) = -a(R)\).
Proof. Let $d$ be the dimension of $R$. First, we assume that the condition (1) holds and we will prove that $c(m) \geq -a(R) - \varepsilon$ for every $\varepsilon > 0$. We may assume by Lemma 2.9 (4) that $k$ is an infinite field. Let $J$ be a minimal reduction of $m$. As $R$ is a Cohen-Macaulay standard graded ring, $J$ is generated by a homogeneous regular sequence of degree one. Then $m^{d+a(R)+1}$ is contained in $J$ but $m^{d+a(R)}$ is not.

It is enough to show that $J^{F^d_m-a(R)-\varepsilon} = J$ by Lemma 2.9 (1) and Lemma 3.3 (1). Let $x \in J^{F^d_m-a(R)-\varepsilon}$, and we may assume that the degree of $x$ is less than or equal to $d + a(R)$. By definition, $m^{[(-a(R)-\varepsilon)(q-1)]} x^q \subseteq J[q]$ for all sufficiently large $q = p^e$. Thus,

$$x^q \in \left(J[q]; J^{(-a(R)-\varepsilon)(q-1)}\right) \subseteq J[q] + J^{dq - [(a(R)-\varepsilon)(q-1)]} - 1,$$

The degree of $x^q$ is less than or equal to $(d + a(R))q$, but $dq - [(a(R)-\varepsilon)(q-1)] - 1$ is greater than $(d + a(R))q$ for sufficiently large $q$, so $x^q$ has to lie in $J[q]$ for such $q$. It then follows from the $F$-injectivity of $R$ that $x \in J$, that is, $J^{F^d_m-a(R)-\varepsilon}$.

Next, we assume that the condition (2) holds and we will show that $c(m) \geq -a(R)$. It is enough to show by Lemma 3.3 (3) that $fpt(m) \geq -a(R)$. Let $X = \text{Proj} R$. Since $R$ is a quasi-Gorenstein normal standard graded ring, there exists a very ample divisor $H$ on $X$ such that $R = \bigoplus_{n \geq 0} H^0(X, \mathcal{O}_X(nH))$ and $K_X \sim a(R)H$. Note that $X$ is globally $F$-split and $a(R) \leq 0$, because $R$ is $F$-pure. It then follows from an argument similar to the proof of [30, Theorem 4.3] that there exists an effective Cartier divisor $D$ on $X$ such that $D \sim (1-p)a(R)H$ and that the composite map

$$\mathcal{O}_X \rightarrow F_* \mathcal{O}_X \rightarrow F_* \mathcal{O}_X(D) \rightarrow \rightarrow F_* x^p \mapsto F_* (sx^p)$$

splits as an $\mathcal{O}_X$-module homomorphism, where $s$ is a defining section for $D$. This map induces the $R$-linear map $R \rightarrow F_* R$ with $1 \mapsto F_* s$, which also splits. Since $s$ belong to $m^{(1-p)a(R)}$ by the definition of $D$, the pair $(R, m^{a(R)})$ is sharply $F$-pure. Thus, $fpt(m) \geq -a(R)$.

Motivated by Conjecture 1.1, we propose the following conjecture.

**Conjecture 3.7.** Let $(R, m)$ be an $F$-finite $F$-pure normal local ring of characteristic $p > 0$. Then $R$ is quasi-Gorenstein if and only if $fpt(m) = c(m)$.

**Remark 3.8.** Conjecture 3.7 can fail if $R$ is not normal. Indeed, [11, Example 5.3] and Proposition 3.6 give a counterexample.

Conjecture 3.7 implies an extension of Conjecture 1.1.

**Proposition 3.9.** Let $R$ be an $F$-pure normal standard graded ring, with $R_0$ an $F$-finite field of characteristic $p > 0$. Let $m$ denote the homogeneous maximal ideal of $R$. Suppose that Conjecture 3.7 holds for the localization $R_m$ of $R$ at $m$. Then $R$ is quasi-Gorenstein if and only if $fpt(m) = -a(R)$.

**Proof.** The “only if” part immediately follows from Lemma 3.3 (3) and Proposition 3.6. We will show the “if” part. Suppose that $fpt(m) = -a(R)$. Then by Remark 3.2, Lemma 3.3 (3) and Proposition 3.6,

$$-a(R) = fpt(m) \leq fpt(m R_m) \leq c(m R_m) = c(m) = -a(R),$$

which implies that $fpt(m R_m) = c(m R_m)$. It then follows from Conjecture 3.7 that $R_m$ is quasi-Gorenstein, which is equivalent to saying that $R$ is quasi-Gorenstein.
Theorem 3.10. Let \((R, \mathfrak{m})\) be an \(F\)-finite normal local ring of characteristic \(p > 0\) and \(\Delta\) be an effective \(\mathbb{Q}\)-divisor on \(X := \text{Spec} R\) such that \((X, \Delta)\) is weakly \(F\)-pure and \(K_X + \Delta\) is \(\mathbb{Q}\)-Cartier of index \(r\). If \(R\) is not quasi-Gorenstein, then

\[
fpt(\Delta; \mathfrak{m}) + \frac{1}{r} \leq c(\mathfrak{m}).
\]

Proof. Let \(d\) be the dimension of \(R\). For every \(fpt(\Delta; \mathfrak{m}) > \varepsilon > 0\) (when \(fpt(\Delta; \mathfrak{m}) = 0\), put \(\varepsilon = 0\), by the definition of \(fpt(\Delta; \mathfrak{a}^t)\) and Lemma 2.4, there exist \(q_0 = p^{\varepsilon_0}\) and \(c\) in \(\mathfrak{m}^{((\varepsilon_0+\varepsilon)(q_0-1))}\) such that

\[
cF_{X, \Delta}^{\varepsilon_0}: H_m^d(\omega_X) \rightarrow H_m^d(\mathcal{O}_X([q_0K_X + (q_0-1)\Delta]))
\]
is injective. We consider the following commutative diagram:

\[
\begin{array}{ccc}
\omega_X \times H_m^d(R) & \longrightarrow & H_m^d(\omega_X) \\
\downarrow & & \downarrow cF_{X, \Delta}^{\varepsilon_0} \\
\mathcal{O}_X([q_0K_X + (q_0-1)\Delta]) \times H_m^d(R) & \longrightarrow & H_m^d(\mathcal{O}_X([q_0K_X + (q_0-1)\Delta])),
\end{array}
\]

where the left vertical map send \((x, z)\) to \((cx^{\varepsilon_0}, F_{H_m^d(R)}^{\varepsilon_0}(z))\).

For each \(1/r > \varepsilon' > 0\), we will show that \(F_{H_m^d(R)}^{\varepsilon_0} \equiv 1/r - \varepsilon - \varepsilon' = 0\), which implies the assertion. Let \(\xi \in \mathfrak{m}^{((\varepsilon_0+\varepsilon)(q_0-1))} F_{H_m^d(R)}^{\varepsilon_0}(\xi) = 0\) for all \(q = p^e \geq q_1\). By the definition of weak \(F\)-purity, we may assume that \(q_0\) is sufficiently large so that \(q_0 \geq q_1\) and \(e(q_0-1) \geq 2\). Since \(R\) is not quasi-Gorenstein, \(r \geq 2\) or \(\Delta\) is strictly effective. In either case, the fractional ideal \(\omega_X^e = \mathcal{O}_X(K_X^r)\) is contained in the fractional ideal \(m\mathcal{O}_X(r(K_X + \Delta))\). Therefore, for all \(x \in \omega_X\), one has

\[
cx^q_0 \in \mathfrak{m}^{((\varepsilon_0+\varepsilon)(q_0-1))} \omega_X^q_0
\]

\[
\subseteq \mathfrak{m}^{((\varepsilon_0+\varepsilon)(q_0-1))} \mathcal{O}_X([q_0K_X + (q_0-1)\Delta])
\]

\[
\subseteq \mathfrak{m}^{((\varepsilon_0+\varepsilon)(q_0-1))} \mathcal{O}_X([q_0K_X + (q_0-1)\Delta]),
\]

by the choice of \(q_0\). Since \(q_0 \geq q_1\),

\[
cx^q_0 F_{H_m^d(R)}^{\varepsilon_0}(\xi) \in \mathfrak{m}^{((\varepsilon_0+\varepsilon)(q_0-1))} \mathcal{O}_X([q_0K_X + (q_0-1)\Delta]) F_{H_m^d(R)}^{\varepsilon_0}(\xi)
\]

\[
= 0 \text{ in } H_m^d(\mathcal{O}_X([q_0K_X + (q_0-1)\Delta])),
\]

and it then follows from the commutativity of the above diagram that \(cF_{X, \Delta}^{\varepsilon_0}(x\xi) = 0\). The injectivity of the map \(cF_{X, \Delta}^{\varepsilon_0}\) implies that \(x\xi = 0\) for all \(x \in \omega_X\). This forces \(\xi\) to be zero, because \(\omega_X \times H_m^d(R) \rightarrow H_m^d(\omega_X)\) is the duality pairing. Thus, \(F_{H_m^d(R)}^{\varepsilon_0} = 0\). \(\square\)

We give an example of a standard graded Cohen-Macaulay ring \(R\) that is \(F\)-pure, with \(a(R) = -1\) and \(fpt(\mathfrak{m}) = 0\); this is based on [33]. The ring \(R\) is \(\mathbb{Q}\)-Gorenstein, with index 2.

Example 3.11. Let \(k\) be a field of characteristic \(p \equiv 1 \mod 4\), and set

\[
S = k[w, x, y, z]/(w^4 + x^4 + y^4 + z^4).
\]
By the characteristic assumption, the ring $S$ is $F$-pure. Set $R$ to be the $k$-subalgebra generated by the monomials

$$w^4, w^3x, w^2x^2, wx^3, x^4, y^4, y^3z, y^2z^2, yz^3, z^4.$$  

Then $R$ is a direct summand of $S$ as an $R$-module: one way to see this is to use the $\mathbb{Z}/4 \times \mathbb{Z}/4$-grading on $S$ under which $\deg w = (1, 0) = \deg x$, and $\deg y = (0, 1) = \deg z$, in which case $R$ is the subring of $S$ generated by elements of degree $(0,0)$. It follows that $R$ is $F$-pure, normal, as well as Cohen-Macaulay.

The ring $R$ has a standard grading under which each of the monomials displayed is assigned degree one. Computing the socle modulo the system of parameters $x^4, y^4, z^4$, it follows that $a(R) = -1$. By Proposition 3.6, we have $c(m) = 1$.

The fractional ideal

$$\omega_R = \frac{1}{w^2x2}(w^3x, w^2x^2, wx^3)(y^3z, y^2z^2, yz^3)$$

is, up to isomorphism, the graded canonical module of $R$; its second symbolic power is

$$\omega_R^{(2)} = \frac{y^2z^2}{w^2x^2} R,$$

so the ring $R$ is $\mathbb{Q}$-Gorenstein. Using Theorem 4.1, one checks that that $\nu_e(m) = 0$ for each $e \geq 1$. It follows that $\text{fpt}(m) = 0$.

**Corollary 3.12.** Let $(R,m)$ be an $F$-finite $F$-pure normal local ring of characteristic $p > 0$.

1. Suppose that there exists an effective $\mathbb{Q}$-divisor $\Delta$ on $X = \text{Spec } R$ such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier, $(X,\Delta)$ is weakly $F$-pure and $\text{fpt}(m) = \text{fpt}(\Delta;m)$. Then Conjecture 3.7 holds for this $R$.

2. If $c(m) = 0$, then $R$ is quasi-$Gorenstein$.

*Proof.* (1) immediately follows from Theorem 3.10. We will show (2). Since $R$ is $F$-pure, then by [30, Theorem 4.3 (ii)], there exists an effective $\mathbb{Q}$-divisor on $X$ such that $(R,\Delta)$ is sharply $F$-pure with $K_X + \Delta$ $\mathbb{Q}$-Cartier. Then

$$0 \leq \text{fpt}(\Delta;m) \leq \text{fpt}(m) \leq c(m) = 0,$$

and the assertion follows from (1). \qed

When is the assumption of Corollary 3.12 (1) satisfied? If the pair $(R, m^{\text{fpt}(m)})$ is weakly $F$-pure, then by an argument similar to the proof of Corollary 3.12, there exists an effective $\mathbb{Q}$-divisor on $X$ such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier and $\text{fpt}(\Delta;m) = \text{fpt}(m)$. That is, the assumption of Corollary 3.12 (1) is satisfied.

**Question 3.13** (cf. [19, Question 3.6]). Let $(R,m)$ be an $F$-finite $F$-pure normal local ring of characteristic $p > 0$. When is the pair $(R,m^{\text{fpt}(m)})$ weakly $F$-pure?

We will show in Proposition 4.13 that if $(R,m)$ is an $F$-pure $\mathbb{Q}$-Gorenstein normal standard graded ring over an $F$-finite field of characteristic $p > 0$ with Gorenstein index not divisible by $p$, then $(R,m^{\text{fpt}(m)})$ is sharply $F$-pure.

We now prove the main result of this section:

**Theorem 3.14.** Let $(R,m)$ be an $F$-finite $F$-pure normal local ring of characteristic $p > 0$. Suppose that the anti-canonical cover $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ of $X := \text{Spec } R$ is Noetherian. Then $\text{fpt}(m) = c(m)$ if and only if $R$ is quasi-$Gorenstein$. 

Proof. Since $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian, one can find an integer $r \geq 1$ satisfying the following: for every $q = p^e$, if we write $q - 1 = rn_e + j_e$ with $n_e \geq 0$ and $r - 1 \geq j_e \geq 0$, then
\[
\mathcal{O}_X((1 - q)K_X) = \mathcal{O}_X(-rK_X)^{n_e} \mathcal{O}_X(-j_eK_X).
\]
Suppose that $R$ is not quasi-Gorenstein, and we will show that $\text{fpt}(m) + \frac{1}{r} \leq c(m)$. Let $\varphi_1, \ldots, \varphi_l$ be a system of generator for $\mathcal{O}_X(-rK_X)$.

For every $\text{fpt}(m) > \varepsilon > 0$, there exist a sufficiently large $q = p^e$ and $c \in m^{[(\text{fpt}(m) - c)(q - 1)]}$ such that the $R$-linear map $R \to F^e_R$ sending $1$ to $F^e_R$ splits (when $\text{fpt}(m) = 0$, put $\varepsilon = 0$ and $c = 1$). That is, there exists an $R$-linear map $\varphi: F^e_R \to R$ sending $F^e_R$ to $1$. It follows from Grothendieck duality that there exists an isomorphism
\[
\Phi: \text{Hom}_R(F^e_R, R) \cong F^e_R \mathcal{O}_X((1 - q)K_X) = F^e_R (\mathcal{O}_X(-rK_X)^{n_e} \mathcal{O}_X(-j_eK_X)).
\]
We write $\Phi(\varphi) = \sum_{m} F^e_R (\varphi_1^{m_1} \cdots \varphi_l^{m_l} \psi_m)$ with $\psi_m \in \mathcal{O}_X((-rK_X)^m)$, where $m$ runs through all elements of $\{(m_1, \ldots, m_l) \in \mathbb{Z}_{\geq 0}^l \mid m_1 + \cdots + m_l = n_e\}$. Then
\[
1 = \varphi(F^e_R) = \Phi^{-1} \left( \sum_{m} F^e_R (\varphi_1^{m_1} \cdots \varphi_l^{m_l} \psi_m) \right) (F^e_R).
\]

Therefore, there exists $m = (m_1, \ldots, m_l) \in \mathbb{Z}_{\geq 0}^l$ with $\sum_{i=1}^l m_i = n_e$ such that $\Phi^{-1}(F^e_R (\varphi_1^{m_1} \cdots \varphi_l^{m_l} \psi_m)) (F^e_R)$ is a unit. Replacing $c$ by a unit multiple, we may assume that $\Phi(\varphi)$ is a unit multiple.

Since $\varphi_i$ determines an effective divisor $D_i$, which is linearly equivalent to $-rK_X$, by an argument similar to the proof of [30, Theorem 4.3], $\varphi$ induces an $R$-linear map $F^e_R \mathcal{O}_X(m_1D_1 + \cdots + m_lD_l) \to R$ sending $F^e_R$ to $1$. Then its Matlis dual
\[
cF^e_R: H^d_m(\omega_R) \to H^d_m(\mathcal{O}_X(qK_X + m_1D_1 + \cdots + m_lD_l))
\]
is injective. On the other hand, since $R$ is not quasi-Gorenstein, the fractional ideal $\omega^e_R = \mathcal{O}_X(K_X)^e$ is contained in $m \mathcal{O}_X(rK_X + D_i)$ for each $i = 1, \ldots, l$. Hence, $\omega^e_R$ is contained in $m^{(q-1)/r}\mathcal{O}_X(qK_X + m_1D_1 + \cdots + m_lD_l)$. It then follows from an analogous argument to the proof of Theorem 3.10 that $\text{fpt}(m) + \frac{1}{r} \leq c(m)$.

Remark 3.15. In the setting of Theorem 3.14, it is well-known that $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian if $R$ is $\mathbb{Q}$-Gorenstein, $R$ is a normal semigroup ring or $R$ is a determinantal ring. We briefly explain the reason why $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian in the latter case.

Let $m$ and $n$ be two positive integers such that $m \leq n$ and let $T$ be a $m \times n$ matrix of indeterminates over a field $k$. Let $S = k[T]$ denote the polynomial ring in $mn$ variables over $k$ and $I$ denote the ideal generated by the $t$-minors of $T$. Set $R = S/I$. Then the anti-canonical class of $R$ is the class of the $(n - m)$-th symbolic power of $J$, where $J$ is the ideal generated (modulo $I$) by the $(t - 1)$-minors of any pre-fixed $t - 1$ rows of $T$ by [7, Theorem 8.8]. Moreover, the symbolic powers of such an ideal $J$ coincide with its ordinary powers by [7, Corollary 9.18], so the anti-canonical cover is the Rees algebra of $J^{n-m}$. In particular, it is Noetherian.

Another case where $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian is the following:

**Corollary 3.16.** Let $X$ be a three-dimensional strongly $F$-regular variety over an algebraically closed field of characteristic $p > 5$ and $x$ be a closed point of $X$. Then $\text{fpt}(m_x) = c(m_x)$ if and only if $X$ is Gorenstein at $x$. 
Proof. We may assume that $X$ is affine. By [30, Theorem 4.3] and [16, Theorem 3.3], there exists an effective $\mathbb{Q}$-divisor $\Delta$ on $X$ such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier and $(X, \Delta)$ is strongly $F$-regular and in particular is klt. Since the minimal model program holds for three-dimensional klt pairs in characteristic $p > 5$, the anti-canonical cover $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian (see for example [9, Theorem 2.28]). Thus, the assertion follows from Theorem 3.14.

A combination of Proposition 3.9, Theorem 3.14, Remark 3.15 and Corollary 3.16 gives an extension of [19, Theorem 1.2 (2)]:

Corollary 3.17. Let $R$ be an $F$-pure normal standard graded ring, with $R_0$ an $F$-finite field of characteristic $p > 0$. Let $m$ be the homogeneous maximal ideal of $R$. Suppose that the anti-canonical cover $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ of $X := \text{Spec } R$ is Noetherian. This assumption is satisfied, for example, in each of the following cases:

(i) $R$ is $\mathbb{Q}$-Gorenstein,
(ii) $R$ is a semigroup ring,
(iii) $R$ is a determinantal ring,
(iv) $R$ is a strongly $F$-regular ring of dimension at most three,
(v) $R$ is a four-dimensional strongly $F$-regular ring and $p > 5$.

Then $\text{fpt}(m) = -a(R)$ if and only if $R$ is quasi-Gorenstein.

Proof. If $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian, then the assertion follows from Proposition 3.9 and Theorem 3.14. By Remark 3.15, $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian in the case of (1), (2) and (3). We will explain why $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian in the case of (4) and (5).

Since two-dimensional strongly $F$-regular rings are $\mathbb{Q}$-Gorenstein, we may assume that $\dim X \geq 3$. Also, since strong $F$-regularity is preserved under flat base change by [1, Theorem 3.6], we may assume that $k$ is algebraically closed field. Let $D$ be a very ample divisor on $Y := \text{Proj } R$ so that $R = \bigoplus_{m \geq 0} H^0(Y, \mathcal{O}_Y(mD))$. It follows from [30, Theorem 1.1] that $Y$ is a normal projective variety of Fano type of dimension at most three. It is known that the minimal model program holds for klt surfaces and also for three-dimensional klt pairs in characteristic $p > 5$ (see [14, 2, 4]). Thus, applying essentially the same argument as the proof of [3, Corollary 1.1.9], we can see that

$$\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X) \cong \bigoplus_{m \in \mathbb{Z}} \bigoplus_{n \geq 0} H^0(Y, \mathcal{O}_Y(mD - nK_Y))$$

is Noetherian.

We also give an answer to [19, Question 6.7]. Before stating the result, we fix some notation. Let $M = \mathbb{Z}^d$, $N = \text{Hom}_\mathbb{Z}(M, \mathbb{Z})$, and denote the duality pairing between $M_R := M \otimes \mathbb{R}$ and $N_R := N \otimes \mathbb{R}$ by $\langle -, - \rangle : M_R \times N_R \rightarrow \mathbb{R}$. Let $\sigma \subset N_R$ be a strongly convex rational polyhedral cone and denote its dual cone by $\sigma^\vee$. Let $R = k[\sigma^\vee \cap M]$ be the affine semigroup ring over a field $k$ defined by $\sigma$ and $m$ be the unique monomial maximal ideal of $R$. The Newton Polyhedron $P(m) \subseteq M_R$ of $m$ is defined as the convex hull of the set of exponents $m \in M$ of monomials $x^m \in m$. We define the function $\lambda_m$ by

$$\lambda_m : \sigma^\vee \rightarrow \mathbb{R} \quad u \mapsto \sup \{ \lambda \in \mathbb{R}_{\geq 0} \mid u \in \lambda P(m) \},$$

where we set $\lambda P(m) = \sigma^\vee$ if $\lambda = 0$, and denote

$$a_{\sigma}(R) := -\min \{ \lambda_m(u) \mid u \in \text{Int}(\sigma^\vee) \cap M \}.$$

Note that $a_{\sigma}(R)$ coincides with the $a$-invariant $a(R)$ if $R$ is standard graded.
Corollary 3.18. We use the above notation. Let \( R = k[\sigma^V \cap M] \) be a (not necessarily standard graded) affine semigroup ring over an \( F \)-finite field \( k \) of characteristic \( p > 0 \) defined by \( \sigma \).

1. Then \( c(\mathfrak{m}) = -a_\sigma(R) \).
2. \( \text{fpt}(\mathfrak{m}) = -a_\sigma(R) \) if and only if \( R \) is Gorenstein.

Proof. Since (2) follows from (1) and Theorem 3.14, we will show only (1). Let \( v_1, \ldots, v_s \) be the primitive generators for \( \sigma \), that is, the first lattice points on the edges of \( \sigma \). Note that the graded canonical module \( \omega_R \) consists of the monomials \( x^\mathfrak{m} \) such that \( \langle m, v_i \rangle \geq 1 \) for all \( i = 1, \ldots, s \). Hence, its \( k \)-dual \( H^d_m(R) \) is written as

\[
H^d_m(R) = \bigoplus_{m \in S} kx^m,
\]

where \( S = \{ m \in M \mid \langle m, v_i \rangle \leq -1 \text{ for all } i = 1, \ldots, s \} \). It follows from the fact that 1 is an \( m^e \)-test element by [17, Theorem 6.4] (see [17, Definition 6.3] for the definition of \( m^e \)-test elements) that the pair \( (R, m^e) \) is \( F \)-rational if and only if for each \( m \in S \), one has \( m|^{p^e}x^{p^em} \neq 0 \) in \( H^d_m(R) \), or equivalently,

\[
(p^em + \lfloor tp^e \rfloor P(m)) \cap S \neq \emptyset,
\]

for infinitely many \( e \). We can rephrase this condition as saying that \(-m \in \text{Int}(tP(m))\), using an argument similar to the proof of [5, Theorem 3]. By Lemma 3.3 (2),

\[
c(\mathfrak{m}) = \sup\{ t \in \mathbb{R}_{\geq 0} \mid (R, m^t) \text{ is } F \text{-rational} \} = \sup\{ t \in \mathbb{R}_{\geq 0} \mid -m \in \text{Int}(tP(m)) \text{ for all } m \in S \} = \min_{u \in -S} \lambda_m(u).
\]

Since \(-S = \text{Int}(\sigma^V) \cap M\), one has the equality \( c(\mathfrak{m}) = -a_\sigma(R) \). \( \square \)

4. Positive characteristic case II

In this section we give a different interpretation of the function \( \nu_e(\mathfrak{m}) \), where \( \mathfrak{m} \) is the homogeneous maximal ideal of an \( F \)-pure normal standard graded domain \( R \) over an \( F \)-finite field (Theorem 4.1). Combining it with the Fedder-type criteria (Proposition 2.5), we give explicit computations of \( \text{fpt}(\mathfrak{m}) \) in many situations (e.g. Propositions 4.3 and 4.5), eventually yielding Corollary 3.17 as a consequence (see Corollary 4.12).

Theorem 4.1. Let \( S \) be an \( n \)-dimensional standard graded polynomial ring over an \( F \)-finite field of characteristic \( p > 0 \). Let \( I \) be a homogeneous ideal such that \( R := S/I \) is an \( F \)-pure normal domain. Let \( \omega_R \) denote the graded canonical module of \( R \). Then, for each \( q = p^e \), one has a graded isomorphism

\[
\frac{I^{[q]}}{I} \cong (\omega_R(n))^{(1-q)}.
\]

In particular, if \( \mathfrak{m} \) is the homogeneous maximal ideal of \( R \), then \(-\nu_e(\mathfrak{m})\) equals the degree of a minimal generator of \( \omega^{(1-q)}_R \) (See Proposition 2.5 for the definition of \( \nu_e(\mathfrak{m}) \)).

Proof. After taking a flat base change, we may assume that \( S = \mathbb{F}[x_1, \ldots, x_n] \), where \( \mathbb{F} \) is a perfect field. It then follows that \( S \) is a free \( S^q \)-module with basis \( x_1^{i_1} \cdots x_n^{i_n} \) where \( 0 \leq i_j \leq q - 1 \) for each \( j \). Consider the homomorphism \( \varphi \in \text{Hom}_{S^q}(S, S^q) \) that maps the basis element \( (x_1 \cdots x_n)^{q-1} \) to 1, and every other basis element to 0. It is readily seen that \( \varphi \) generates \( \text{Hom}_{S^q}(S, S^q) \) as an \( S \)-module.
Let $J$ be the ideal of $S^q$ consisting of $q$-th powers of elements of $I$; note that $JS = I^{[q]}$. Then
\[
\text{Hom}_{S^q}(S/I, S^q/J) \cong \frac{I^{[q]}:S I}{I^{[q]}} \varphi,
\]
see [12, page 465]. Next, note that one has graded isomorphisms
\[
\text{Hom}_{S^q}(S/I, S^q/J) \cong \text{Hom}_{R^q}(R, R^q)
\]
\[
\cong \text{Hom}_{R^q}(R, \text{Hom}_{R^q}(\omega_{R^q}, \omega_{R^q}))
\]
\[
\cong \text{Hom}_{R^q}(R \otimes_R \omega_{R^q}, \omega_{R^q})
\]
\[
\cong \text{Hom}_{R^q}(\omega_R^{(q-1)}, \omega_{R^q})
\]
\[
\cong \text{Hom}_{R^q}(\omega_R^{(q-1)} \otimes_R R, \omega_{R^q})
\]
\[
\cong \text{Hom}_{R}(\omega_R^{(q-1)}, \text{Hom}_{R^q}(R, \omega_{R^q}))
\]
\[
\cong \text{Hom}_{R}(\omega_R^{(q-1)}, \omega_R)
\]
\[
\cong \omega_R^{(1-q)}.
\]

Since the homomorphism $\varphi$ has degree $n - nq$, the desired isomorphism follows.

Suppose $\omega_R^{(1-q)}$ is generated in degrees $-d_1 < \cdots < -d_r$, then $(I^{[q]}:S I)/I^{[q]}$ is generated in degrees $n(q-1) - d_1 < \cdots < n(q-1) - d_r$. Hence the least degree of a homogeneous element of $I^{[q]}:S I$ that is not in $m^{[q]}$ belongs to the set
\[
\{n(q-1) - d_1, \ldots, n(q-1) - d_r\},
\]
and $I^{[q]}:S I \subseteq m^{n(q-1) - d_1}$. Since the definition of $\nu_e(m)$ translates as
\[
\nu_e(m) = \max\{r \in \mathbb{N} \mid (I^{[q]}:S I) \not\subseteq m^{[q]} + m^{n(q-1)-1+r}\},
\]
it follows that $\nu_e(m) \in \{d_1, \ldots, d_r\}$. \hfill \Box

As immediate consequence we get:

**Corollary 4.2.** If $R$ is an $F$-pure quasi-Gorenstein standard graded normal domain, over an $F$-finite field, with homogeneous maximal ideal $m$, then
\[
\text{fpt}(m) = -a(R).
\]
In particular, by Proposition 3.5, in this case $a(R) \geq a_i(R)$ for all $i = 0, \ldots, \dim R$.

**Proposition 4.3.** Let $R$ be the determinantal ring $\mathbb{F}[X]/I$, where $\mathbb{F}$ is an $F$-finite field, the matrix of indeterminates $X$ has size $m \times n$ with $m \leq n$, and $I$ is the ideal generated by the size $t$ minors of $X$ where $1 \leq t \leq m$. Let $m$ be the homogeneous maximal ideal of $R$. Then
\[
\text{fpt}(m) = m(t-1).
\]

**Remark 4.4.** In the notation of the proposition, the ring $R$ has $a$-invariant $-n(t-1)$. It follows that $\text{fpt}(m) = -a(R)$ precisely when $m = n$ or $t = 1$, i.e., if and only if $R$ is Gorenstein.

In the case $t = 2$, the $F$-pure threshold has been calculated previously, see [8, Corollary 1] or [19, Example 6.2]. Since $I$ is a homogeneous ideal of $\mathbb{F}[X]$, which is $F$-pure, one can also ask for $\text{fpt}(I)$. This threshold has been computed in [27] (see [18] for various generalizations):
\[
\text{fpt}(I) = \min \left\{ \frac{(m-k)(n-k)}{t-k} : k = 0, \ldots, t-1 \right\}.
\]
Proof of Proposition 4.3. The graded canonical module of $R$ is computed in [6, Corollary 1.6], namely, it equals $q^{n-m}(m-nt)$, where $q$ is the prime ideal generated by the size $t-1$ minors of the first $t-1$ columns of $X$. The divisor class group of $R$ is described by [7, Corollary 7.10], from which it follows that $\omega^{(1-q)}_R$ is generated by elements of degree $-m(q-1)(t-1)$. Theorem 4.1 now gives

$$\nu_e(m) = m(q-1)(t-1),$$

from which the result follows. □

**Proposition 4.5.** Let $R$ be an $F$-pure $\mathbb{Q}$-Gorenstein standard graded normal domain, over an $F$-finite field, with homogeneous maximal ideal $m$. If $c$ is the order of $\omega_R$ in the divisor class group and $\omega^{(c)}$ is generated in degree $D$, then:

$$\text{fpt}(m) = D/c.$$

In particular, $\text{fpt}(m) = -a(R)$ if and only if $R$ is quasi-Gorenstein.

**Proof.** For $q = p^e$ let us write $1 - q = a(q)c + b(q)$, with $0 \leq b(q) < c$. By the assumptions we have:

$$\omega^{(1-q)}_R = \left(\omega^{(c)}_R\right)^{a(q)} \omega^{(b(q))}_R.$$

In particular, $\omega^{(1-q)}_R$ is generated in degrees $d$ satisfying:

$$a(q)D + A \leq d \leq a(q)D + B,$$

where the minimal generators of $\omega^{(b(q))}_R$ have degrees between $A$ and $B$. Therefore

$$-a(q)D - B \leq \nu_e(m) \leq -a(q)D - A,$$

and $\text{fpt}(m) = \lim_{q \to \infty} \nu_e(m)/q = D/c$.

For the last part of the statement, simply notice that, if $\omega^{(c)}_R$ is principal but $\omega_R$ is not, then the generator of $\omega^{(c)}_R$ must have degree less than $-a(R)c$, since $\omega^{(c)}_R \subseteq \omega^c_R$. □

**Remark 4.6.** In the above notation, if $c = p$ notice that $a(q) = -q/p$ and $b(q) = 1$. Furthermore $A$ can be chosen to be minus the $a$-invariant of $R$, so:

$$\nu_e(m) \leq (q/p)D + a(R) = (q - 1)D/p + D/p + a(R) = (q - 1)\text{fpt}(m) + \text{fpt}(m) + a(R).$$

Given a finitely generated graded $R$-module $M$, we denote by $\delta(M)$ the least integer $d$ such that $M_d \neq 0$. In the case in which $R$ is a normal domain, the canonical module $\omega_R$ is isomorphic (as a graded module) to a divisorial ideal of $R$.

**Lemma 4.7.** If $R$ is a normal standard graded domain, and $a$ a graded divisorial ideal, then:

(i) $\delta(a^{(-1)}) \geq -\delta(a)$.

(ii) $\delta(a^{(-1)}) = -\delta(a)$ if and only if $a$ is principal.

**Proof.** Let $a = (a_1, \ldots, a_r)$, where the $a_i$ are homogeneous elements of the quotient field of $R$ of degree $d_i \in \mathbb{Z}$, where $\delta(a) = d_1 \leq d_2 \leq \ldots \leq d_r$. If $b \in a^{(-1)}$ is a homogeneous nonzero element of degree $k$, then $k + d_1 \geq 0$ since $a_1 b$ is a homogeneous nonzero element of $R$. This shows (i).

Concerning point (ii), if $b$ is a homogeneous nonzero element of $a^{(-1)}$ of degree $-d_1$, then $ba_1 = u$ is a unit of $R$. Because $ba_i = f_i \in R$ for all $i = 1, \ldots, r$, we have $a_i = u^{-1} f_i a_1$ for all $i = 1, \ldots, r$, so that $a_1$ generates $a$ as an $R$-module. □
Proposition 4.8. Let $R$ be an $F$-pure standard graded normal domain, over an $F$-finite field, with homogeneous maximal ideal $m$. Then:

$$\nu_e(m) \leq a(R)(1 - q) \quad \forall q = p^e.$$ 

In particular $fpt(m) \leq -a(R)$. Further, if $R$ is not quasi-Gorenstein, then:

$$\nu_e(m) < a(R)(1 - q) \quad \forall q = p^e.$$ 

Proof. For the first part of the statement, notice that $\delta\left(\omega_R^{(q-1)}\right) \leq \delta\left(\omega_R^{q-1}\right) = a(R)(q - 1) = -a(R)(q - 1)$, so $\delta\left(\omega_R^{(1-q)}\right) \geq a(R)(q - 1)$ by Lemma 4.7, and $\nu_e(m) \leq a(R)(1 - q)$ by Theorem 4.1.

For the second part, assume that $\nu_e(m) = a(R)(1 - q)$ for some $q = p^e$. Since $\delta\left(\omega_R^{(q-1)}\right) \leq a(R)(1 - q)$, by putting together Theorem 4.1 and Lemma 4.7, $\omega_R^{(q-1)}$ must be principal and generated in degree $-a(R)(q - 1)$. Notice that $\omega_R^{(q-1)} \supseteq \omega_R^{q-1}$ and $\delta\left(\omega_R^{q-1}\right) = a(R)(1 - q)$.

Therefore the only possibility is that $\omega_R^{(q-1)} = \omega_R^{q-1}$, so that $\omega_R$ must be principal itself. □

Proposition 4.9. Let $R$ be an $F$-pure standard graded normal domain, over an $F$-finite field, with homogeneous maximal ideal $m$. If the anti-canonical cover $\bigoplus_{k \geq 0} \omega_R^{(-k)}$ of $R$ is Noetherian, then $fpt(m) = -a(R)$ if and only if $R$ is quasi-Gorenstein.

Proof. If the anti-canonical cover of $R$ is Noetherian, then there exists a positive integer $e$ such that, if we write $1 - q = a(q)c - b(q)$ with $a(q)$ positive and $0 \leq b(q) < c$:

$$\omega_R^{(1-q)} = \left(\omega^c\right)^{a(q)} \omega_R^{(1-b(q))}.$$ 

Let us say that $\omega^c$ is generated in degrees $-d_1 < \ldots < -d_r$. Furthermore, let $-e_1 < \ldots < -e_s$ be the degrees of the minimal generators of $R, \omega^{(-1)}, \ldots, \omega^{(-c+1)}$. We have that

$$\nu_e(m) \in \{a(q)d_i + e_j : i = 1, \ldots, r \text{ and } j = 1, \ldots, s\} \quad \forall q = p^e.$$ 

By choosing $i \in \{1, \ldots, r\}$ such that $\nu_e(m) = a(q)d_i + e_j$ (for some $j$) for infinitely many $q$, then

$$fpt(m) = \lim_{q \to \infty} \nu_e(m)/q = d_i/c.$$ 

For the second part of the statement, simply note that if $R$ is not quasi-Gorenstein, with the above notation we have $-d_i \geq -d_1 > a(R)c$ by (the same argument of) Corollary 4.8. □

Remark 4.10. The above argument shows also that $fpt(m)$ is a rational number whenever the assumptions of the corollary are satisfied; this was already known by [9].

Proposition 4.11. Let $R$ be an $F$-pure standard graded normal domain, over an $F$-finite field, with homogeneous maximal ideal $m$. If there exists a positive integer $e$ such that $\delta\left(\omega^c\right) < -a(R)c$, then $fpt(m) < -a(R)$.

Proof. Let $\delta\left(\omega^c\right) = D$. With the same notation of the proof above $q - 1 = a(q)c + b(q)$, so:

$$\delta(\omega_R^{(q-1)}) \leq a(q)D + \delta\left(\omega_R^{(b(q))}\right).$$

Then, using Theorem 4.1 together with Lemma 4.7, for such $q$:

$$\nu_e(m) \leq a(q)D.$$ 

Thus, $fpt(m) = \lim_{q \to \infty} \nu_e(m)/q \leq D/c < -a(R)$. □
The following provides strong evidence for the conjecture of Hara-Yoshida-Watanabe 1.1 and, more generally, for the standard graded case of Conjecture 3.7.

**Corollary 4.12.** Let $R$ be an $F$-pure standard graded normal domain, over an $F$-finite field, with homogeneous maximal ideal $m$. Suppose that one of the following is satisfied:

(i) The anti-canonical cover $\bigoplus_{k \geq 0} \omega^{(-k)}_R$ of $R$ is noetherian.

(ii) For some positive integer $c$, there is a nonzero element of $\omega^{(c)}_R$ of degree $< -a(R)c$. Then $\text{fpt}(m) = -a(R)$ if and only if $R$ is quasi-Gorenstein.

The following gives an extension of [19, Proposition 3.4].

**Proposition 4.13.** Let $R$ be an $F$-pure standard graded normal domain, over an $F$-finite field, with homogeneous maximal ideal $m$. Suppose that the $c$-th Veronese of the anti-canonical cover of $R$ is standard graded and $c$ is not a multiple of $p$. Then $\nu_e(m) = (p^e - 1)\text{fpt}(m)$ for infinitely many positive integers $e$. In particular, $(R, m^{\text{fpt}(m)})$ is sharply $F$-pure.

**Proof.** Since $p$ does not divide $c$, there is an infinite subset $A \subseteq \{p^e : e \in \mathbb{N}\}$ such that $q - 1 = a(q)c$ for all $q \in A$, with $a(q) \in \mathbb{N}$. For such $q$

$$\omega^{(1-q)}_R = \left(\omega^{(-c)}_R\right)^{a(q)}.$$ 

So if $\omega^{(-c)}$ is generated in degrees $-d_1 < \ldots < -d_r$, then

$$\nu_e(m) \in \{a(q)d_i : i = 1, \ldots, r\} \quad \forall \; q \in A.$$ 

So there exists $i$ such that $\text{fpt}(m) = d_i/c$, and for all but finitely many $q \in A$

$$\nu_e(m) = (q - 1)\text{fpt}(m).$$

□

5. **Characteristic zero case**

We prove a characteristic zero analogue of Conjecture 1.1. First, we define a variant of multiplier submodules:

**Definition 5.1.** Let $X$ be a normal variety over a field of characteristic zero, and $a$ be a nonzero coherent ideal sheaf on $X$. Let $\pi : Y \to X$ be a log resolution of $(X, a)$, that is, $\pi$ is a proper birational morphism from a smooth variety $Y$ such that $a\mathcal{O}_Y = \mathcal{O}_Y(-F)$ is invertible and $\text{Exc}(\pi) \cup \text{Supp}(F)$ is a simple normal crossing divisor. Let $E$ be the reduced divisor supported on $\text{Exc}(\pi)$. For a real number $t \geq 0$, the multiplier submodule $\mathcal{J}(\omega_X, a^t)$ is defined by

$$\mathcal{J}(\omega_X, a^t) := \pi_*\omega_Y([-tF]) \subseteq \omega_X.$$ 

This submodule of $\omega_X$ is independent of the choice of $\pi$, see, for example, the proof of [31, Proposition 3.4]. When $a = \mathcal{O}_X$ or $t = 0$, we simply denote $\mathcal{J}(\omega_X, a^t)$ by $\mathcal{J}(\omega_X)$.

As a variant of $\mathcal{J}(\omega_X, a^t)$, we define the submodule $\mathcal{I}(\omega_X, a^t)$ of $\omega_X$ by

$$\mathcal{I}(\omega_X, a^t) := \begin{cases} 
\pi_*\omega_Y([-\varepsilon E - (t - \varepsilon)F]) & \text{if } t > 0 \\
\pi_*\omega_Y([-E]) & \text{if } t = 0 
\end{cases}$$ 

for sufficiently small $\varepsilon > 0$. It is easy to see that $\mathcal{I}(\omega_X, a^t)$ is independent of the choice of $\varepsilon$ if $\varepsilon > 0$ is sufficiently small. When $a = \mathcal{O}_X$ or $t = 0$, we simply denote $\mathcal{I}(\omega_X, a^t)$ by $\mathcal{I}(\omega_X)$.

**Lemma 5.2.** $\mathcal{I}(\omega_X, a^t)$ is independent of the choice of the resolution.
Proof. We consider the case where $t > 0$; the case $t = 0$ follows from a similar argument. Let $f : Y \rightarrow X$ be a log resolution of $(X, a)$ such that $a\mathcal{O}_X = \mathcal{O}_X(-F)$ is invertible, and let $E_Y$ be the reduced divisor supported on $\text{Exc}(f)$. Let $g : Z \rightarrow Y$ be a log resolution of $(Y, E_Y + F)$, and let $E_Z$ be the reduced divisor supported on $\text{Exc}(g)$. Then it is enough to show that

$$\omega_Y([\varepsilon E_Y - (t - \varepsilon)F]) = g_*\omega_Z([\varepsilon'(g^{-1}_*E_Y + E_Z) - (t - \varepsilon')g^*F])$$

for sufficiently small real numbers $\varepsilon, \varepsilon' > 0$, since two log resolutions of $(X, a)$ can be dominated by a third log resolution. Let $\bigcup_i E_i$ be the irreducible decomposition of $\text{Supp}(E_Y + F)$. For sufficiently small $\varepsilon > 0$, we can write

$$[K_Y + \varepsilon E_Y - (t - \varepsilon)F] = K_Y - tF + \sum_i a_i E_i,$$

where $1 \geq a_i > 0$ for all $i$. Since $\sum_i E_i$ is a simple normal crossing divisor on $Y$, the pair $(Y, \sum_i a_i E_i)$ is log canonical. By the definition of log canonical pairs, we have

$$G := [K_Z + \varepsilon'(g^{-1}_*E_Y + E_Z) - (t - \varepsilon')g^*F] - g^*[K_Y + \varepsilon E_Y - (t - \varepsilon)F]$$

is a simple normal crossing divisor on $Y$. Therefore,

$$g_*\omega_Z([\varepsilon'(g^{-1}_*E_Y + E_Z) - (t - \varepsilon')g^*F]) = g_* (\omega_Y([\varepsilon E_Y - (t - \varepsilon)F]) \otimes \mathcal{O}_Z(G))$$

\[= \omega_Y([\varepsilon E_Y - (t - \varepsilon)F]) \otimes g_* \mathcal{O}_Z(G)
= \omega_Y([\varepsilon E_Y - (t - \varepsilon)F]).\]

\[\square\]

Remark 5.3. Let $X$ be a normal variety over a field of characteristic zero.

1. Then $X$ has only rational singularities if and only if $X$ is Cohen-Macaulay and $\mathcal{J}(\omega_X) = \omega_X$, see [24, Theorem 5.10].
2. If $X$ has only Du Bois singularities, then $\mathcal{I}(\omega_X) = \omega_X$, see [25]. In case $X$ is Cohen-Macaulay, the converse holds as well. The reader is referred to [28] for the definition and a simple characterization of Du Bois singularities.

Using $\mathcal{I}(\omega_X, a^t)$, we define a new invariant of singularities in characteristic zero:

Definition 5.4. Let $X$ be a normal variety over a field of characteristic zero, and $a$ a nonzero coherent ideal sheaf on $X$. Suppose that $X$ has only Du Bois singularities. Then the threshold $d(a)$ is defined by

$$d(a) := \sup \{ t \geq 0 \mid \mathcal{I}(\omega_X, a^t) = \omega_X \}.$$

If $x$ is a point of $X$, then the threshold $d_x(a)$ is defined by

$$d_x(a) := \sup \{ t \geq 0 \mid \mathcal{I}(\omega_X, a^t)_x = \omega_{X,x} \}.$$

Remark 5.5. Let $R$ be a standard graded ring with $R_0$ a field $k$ of characteristic zero, and let $m$ be the homogeneous maximal ideal of $R$. Let $X = \text{Spec } R$ and $x \in X$ be the closed point corresponding to $m$. By considering a $k^*$-equivariant log resolution of $(X, m)$, we see that $\mathcal{I}(\omega_X, m^t)$ is a graded submodule of the graded canonical module $\omega_R$. This implies that $d(m) = d_x(m)$.

de Fernex-Hacon extended the notion of log canonical thresholds to the non-$\mathbb{Q}$-Gorenstein setting; we recall their definition:
Definition 5.6 ([10, Proposition 7.2]). Let $X$ be a normal variety over a field of characteristic zero, $a \subset O_X$ a nonzero coherent ideal sheaf, and $t \geq 0$ a real number.

(1) The pair $(X, a^t)$ is said to be klt (resp. log canonical) in the sense of de Fernex-Hacon if there exists an effective $\mathbb{Q}$-divisor on $X$ such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier and $((X, \Delta); a^t)$ is klt (resp. log canonical) in the classical sense. That is, if $\pi: Y \to X$ is a log resolution of $(X, \Delta, a)$ such that $aO_Y = O_Y(-F)$ is invertible and if we write

$$K_Y - \pi^*(K_X + \Delta) - tF = \sum a_i E_i$$

where the $E_i$ are prime divisors on $Y$ and the $a_i$ are real numbers, then $a_i > -1$ (resp. $a_i \geq -1$) for all $i$. The log canonical threshold $\text{lt}_t(a)$ of $a$ is defined by

$$\text{lt}_t(a) := \sup \{t \geq 0 \mid (X, a^t) \text{ is log canonical in the sense of de Fernex-Hacon}\}.$$

(2) Suppose that $x$ is a point of $X$. Then $(X, a^t)$ is klt (resp. log canonical) at $x$ in the sense of de Fernex-Hacon if there exists an open neighborhood $U$ of $x$ such that $(U, (a|_U)^t)$ is klt (resp. log canonical) in the sense of de Fernex-Hacon. If, in addition, $a = O_X$, then we say that $(X, x)$ is a log terminal (resp. log canonical) singularity in the sense of de Fernex-Hacon. The log canonical threshold $\text{lt}_x(a)$ of $a$ at $x$ is defined by

$$\text{lt}_x(a) := \sup \{t \geq 0 \mid (X, a^t) \text{ is log canonical at } x \text{ in the sense of de Fernex-Hacon}\}.$$ 

If $\Delta$ is an effective $\mathbb{Q}$-divisor on $X$ such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier and $(X, \Delta)$ is log canonical at $x$ (in the classical sense), then the threshold $\text{lt}_x(\Delta; a)$ is defined by

$$\text{lt}_x(\Delta; a) := \sup \{t \geq 0 \mid ((X, \Delta); a^t) \text{ is log canonical at } x \text{ (in the classical sense)}\}.$$ 

We prove some basic properties of $d_x$.

Lemma 5.7. Let $(X, x)$ be a $d$-dimensional normal singularity over a field of characteristic $0$.

(1) If $(X, x)$ is a rational singularity, then

$$d_x(a) = \sup \{t \geq 0 \mid J(\omega_x, a^t)_x = \omega_{x,x}\}.$$ 

(2) Suppose that $(X, x)$ is a log canonical singularity in the sense of de Fernex-Hacon. Then $\text{lt}_x(a) \leq d_x(a)$. In addition, if $X$ is quasi-Gorenstein at $x$, then $\text{lt}_x(a) = d_x(a)$.

(3) Suppose that $(X, x)$ is a Cohen-Macaulay Du Bois singularity. Then $d_x(m_x) \leq d$. If $J \subset O_{X,x}$ is a minimal reduction of the maximal ideal $m_x$, then $m_x^{d+1-d_x(m_x)} \subset J$.

(4) Suppose that $X$ is Cohen-Macaulay at $x$. If $d_x(m_x) > d - 1$, then $X$ is nonsingular at $x$ and in particular $d_x(m_x) = d$.

Proof. (1) Shrinking $X$ if necessary, we may assume that $X$ has only rational singularities. First we will check that $d_x(a) > 0$. Let $\pi: Y \to X$ be a log resolution of $(X, a)$ such that $aO_Y = O_Y(-F)$ is invertible and let $E$ be the reduced divisor supported on $\text{Exc}(\pi)$. For sufficiently small $t > \varepsilon > 0$,

$$K_Y + E \geq [K_Y + \varepsilon E - (t - \varepsilon)F] \geq K_Y.$$ 

Taking the pushforward $\pi_*$, we obtain inclusions $\omega_X \supset I(\omega_X, a^t) \supset J(\omega_X) = \omega_X$ by Remark 5.3 (1). That is, $d_x(a) \geq t > 0$.

Now we will show the assertion. Since $J(\omega_X, a^t) \subset I(\omega_X, a^t)$, the inequality

$$d_x(a) \geq \sup \{t \geq 0 \mid J(\omega_X, a^t)_x = \omega_{x,x}\}$$

is obvious. We will prove the reverse inequality. It is enough to show that if $I(\omega_X, a^t)_x = \omega_{x,x}$ with $t > 0$, then $\omega_x^{a^t - \varepsilon} = \omega_{x,x}$ for all $t \geq \varepsilon > 0$. Fix a real number $t \geq \varepsilon > 0$. 

Shrinking $X$ again if necessary, we may assume that $X$ is affine and that $\mathcal{I}(\omega_X, a') = \omega_X$. This means that for sufficiently small $(1/2)\varepsilon \geq \varepsilon' > 0$,

$$\text{ord}_{E_i}(K_Y + \text{div}_Y(f) + \varepsilon'E - (t - \varepsilon')F) > -1$$

for every prime divisor $E_i$ on $Y$ and for every $f \in \omega_X$. If $E_i$ is an irreducible component of $\text{Supp} F$, then

$$\text{ord}_{E_i}(K_Y + \text{div}_Y(f) - (t - \varepsilon)F) \geq \text{ord}_{E_i}(K_Y + \text{div}_Y(f) + \varepsilon'E - (t - \varepsilon')F) > -1.$$  

On the other hand, since $X$ has only rational singularities, $K_Y + \text{div}_Y(f) \geq 0$ by Remark 5.3 (1). Therefore, if $E_i$ is not a component of $\text{Supp} F$, then

$$\text{ord}_{E_i}(K_Y + \text{div}_Y(f) - (t - \varepsilon)F) = \text{ord}_{E_i}(K_Y + \text{div}_Y(f)) \geq 0.$$  

Summing up above, we conclude that $[K_Y + \text{div}_Y(f) - (t - \varepsilon)F] \geq 0$ for every $f \in \omega_X$, that is, $\mathcal{I}(\omega_X, a^{t-\varepsilon}) = \omega_X$.

(2) For the former assertion, it is enough to show that if $(X, a')$ is log canonical at $x$ in the sense of de Fernex-Hacon, then $\mathcal{I}(\omega_X, a') = \omega_{X,x}$. Shrinking $X$ if necessary, we may assume that $X$ is affine and there exists an effective $\mathbb{Q}$-divisor $\Delta$ on $X$ such that $((X, \Delta);a')$ is log canonical with $K_X + \Delta$ $\mathbb{Q}$-Cartier of index $r$. Let $\pi: Y \to X$ be a log resolution of $(X, \Delta, a)$ such that $a\mathcal{O}_Y = \mathcal{O}_Y(-F)$ is invertible and let $E$ be the reduced divisor supported on $\text{Exc}(\pi)$. By the definition of log canonical pairs,

$$[K_Y - \pi^*(K_X + \Delta) + \varepsilon_1 E - (t - \varepsilon)F] \geq 0$$

for every $\varepsilon_1 > 0$ and $t \geq \varepsilon_2 > 0$ (when $t = 0$, put $\varepsilon_2 = 0$). Let $f \in \omega_X$. Since the fractional ideal $\omega^f_X$ is contained in $\mathcal{O}_X(\pi(K_X + \Delta))$, one has $\text{div}_Y(f) + \pi^*(K_X + \Delta) \geq 0$. It follows from these two inequalities that

$$[K_Y + \varepsilon_1 E - (t - \varepsilon)F] + \text{div}_Y(f) \geq 0,$$

which implies that $f \in \mathcal{I}(\omega_X, a')$.

Now we will show the latter assertion. Shrinking $X$ again if necessary, we may assume that $\omega_X \cong \mathcal{O}_X$. Then $\mathcal{I}(\omega_X, a')$ can be identified with the maximal non-lc ideal $\mathcal{J}'(X, a')$ under this isomorphism (see [13, Definition 7.4] for the definition of $\mathcal{J}'(X, a')$). Since $\mathcal{J}'(X, a') = \mathcal{O}_X$ if and only if $(X, a')$ is log canonical by the definition of $\mathcal{J}'(X, a')$, one has the equality that $\text{lc}_x(a) = d_x(a)$.

(3) The proof is essentially the same as that of [32, Theorem 5.2.5]. Let $f: Y \to \text{Spec} \mathcal{O}_{X,x}$ be the blow-up at $m_x$ with exceptional divisor $F_x$. Take a log resolution $\pi: \tilde{X} \to \text{Spec} \mathcal{O}_{X,x}$ of $m_x$. Then there exists a morphism $g: \tilde{X} \to Y$ such that $\pi = f \circ g$. Let $E = \sum_{i=1}^s E_i$ be the reduced divisor supported on $\text{Exc}(\pi)$. We may assume that $E_1, \ldots, E_r$ are all the components of $E$ dominating an irreducible component of $F_x$, and put $E' := \sum_{i=r+1}^s E_i$. If $t > d$, then

$$\mathcal{I}(\omega_X, m^t_x)_x = \pi_* \mathcal{O}_{\tilde{X}}([K_{\tilde{X}} + \varepsilon E - (t - \varepsilon)g*F_x])$$

$$\subseteq \pi_* \mathcal{O}_{\tilde{X}}([K_{\tilde{X}} + E' - dg*F_x])$$

$$= f_* (g_* \mathcal{O}_{\tilde{X}}(K_{\tilde{X}} + E') \otimes \mathcal{O}_Y(-dF_x))$$

$$\subseteq f_* \omega_Y(-dF_x)$$

$$= f_* m^d_x \omega_Y$$

for sufficiently small $\varepsilon > 0$. It follows from [20, Theorem 3.7] and [21, Lemma 5.1.6] that

$$\mathcal{I}(\omega_X, m^t_x)_x : \mathcal{O}_{X,x} \omega_{X,x} \subseteq f_* m^d_x \omega_Y : \mathcal{O}_{X,x} \omega_{X,x} = \text{core}(m),$$
where core(m) is the intersection of all reductions of m. In particular, $\mathcal{I}(\omega_X, m_x^t) \subseteq \omega_{X,x}$, that is, $d_x(m_x) < t$. Thus, $d_x(m_x) \leq d$.

Since $\mathcal{I}(\omega_X, m_x^{d_x(m_x)-\varepsilon}) = \omega_{X,x}$ for every $\varepsilon > 0$ (we put $\varepsilon = 0$ when $d_x(m_x) = 0$), by the same argument as above,

$$m_x^{d+1-[d_x(m_x)]} \omega_{X,x} = m_x^{d+1-[d_x(m_x)]} \mathcal{I}(\omega_X, m_x^{d_x(m_x)-\varepsilon}) \subseteq f_x m_x^d \omega_Y$$

for sufficiently small $\varepsilon > 0$. It then follows from [20, Theorem 3.7] and [21, Lemma 5.1.6] again that

$$m_x^{d+1-[d_x(m_x)]} \subseteq f_x m_x^d \omega_Y : O_{X,x} \omega_{X,x} = \text{core}(m) \subseteq J.$$

(4) Let $J$ be a minimal reduction of $m_x$. It then follows from (3) that $m_x = J$, which means that $m_x$ is generated by at most $d$ elements, that is, $X$ is nonsingular at $x$. If $X$ is nonsingular at $x$, then by (2), we see that $d_x(m_x) = \text{lct}(m_x) = d$. $\Box$

We can compute the log canonical threshold of the maximal ideal of an affine determinantal variety using $F$-pure thresholds:

**Proposition 5.8.** Let $D_{m,n,t} := \text{Spec} k[X]/I_t$ be the affine determinantal variety over an algebraically closed field $k$ of characteristic zero, where $X$ is an $m \times n$ matrix of indeterminates with $m \leq n$. Set $I_t$ to be the ideal generated by the size $t$-minors of $X$, where $1 \leq t \leq m$. Let $m$ be the homogeneous maximal ideal of $k[X]/I_t$, corresponding to the origin $0$ in $D_{m,n,t}$. Then $\text{lct}(m) = m(t-1)$.

**Proof.** For each prime number $p$, let $R_p := \mathbb{F}_p[X]/I_{t,p}$ be the modulo $p$ reduction of $k[X]/I_t$, and $m_p$ the homogeneous maximal ideal of $R_p$. It follows from [9, Corollary 6.6] and Theorem 4.3 that

$$\text{lct}(m) = \lim_{\varepsilon \to \infty} \text{fpt}(m_p) = m(t-1).$$

$\Box$

**Proposition 5.9.** Let $x \in X$ be a closed point of a normal variety $X$ over a field of characteristic zero, and $\Delta$ be an effective $\mathbb{Q}$-divisor on $X$ such that $(X, \Delta)$ is log canonical at $x$ with $K_X + \Delta$ being $\mathbb{Q}$-Cartier of index $r$. If $X$ is not quasi-Gorenstein at $x$, then

$$\text{lct}(\Delta; m_x) + \frac{1}{r} \leq d_x(m_x).$$

In particular, if $d_x(m_x) = 0$, then $X$ is quasi-Gorenstein at $x$.

**Proof.** Shrinking $X$ if necessary, we may assume that $X$ is affine and that $(X, \Delta)$ is log canonical. Let $\pi : Y \to X$ be a log resolution of $(X, \Delta, m_x)$ such that $m_x O_X = O_Y(-F_x)$ is invertible, and let $E$ be the reduced divisor supported on $\text{Exc}(\pi)$. Putting $t = \text{lct}(\Delta; m_x)$, one has the inequality

$$[K_Y - \pi^*(K_X + \Delta) - tF_x + \varepsilon E] \geq 0$$

for every $\varepsilon > 0$. On the other hand, since $X$ is not quasi-Gorenstein at $x$, the fractional ideal $\omega^*_X$ is contained in $m_x O_X(r(K_X + \Delta))$. Hence, for each $f \in \omega_X$, one has the inequality

$$r \text{div}_Y(f) + r\pi^*(K_X + \Delta) - F_x \geq 0.$$
for all $\varepsilon > 0$ and all $f \in \omega_X$. This means that $\mathcal{I}(\omega_X, m_x^{\text{lct}}(\Delta; m_x)+1/r) = \omega_X$, that is, $d_x(m_x) \geq \text{lct}_x(\Delta; m_x) + 1/r$. □

The following theorem is the main result of this section; this is a characteristic zero analogue of Theorem 3.14.

**Theorem 5.10.** Let $(X, x)$ be a log canonical singularity, in the sense of de Fernex-Hacon, over an algebraically closed field of characteristic zero. Suppose that the anti-canonical cover $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)_x$ is Noetherian. Then $\text{lct}_x(m_x) = d_x(m_x)$ if and only if $(X, x)$ is quasi-Gorenstein.

**Proof.** Since the “if” part immediately follows from Lemma 5.7 (2), we will show the “only if” part. Shrinking $X$ if necessary, we may assume that $X$ is log canonical in the sense of de Fernex-Hacon and that $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)$ is Noetherian. Then one can find an integer $r \geq 1$ such that $\mathcal{O}_X(-rmK_X) = \mathcal{O}_X(-rK_X)^m$ for every integer $m \geq 1$. Fix a real number $\varepsilon$ with $\min\{\text{lct}(m_x), 1/r\} > \varepsilon > 0$; when $\text{lct}(m_x) = 0$, put $\varepsilon = 0$. Since $(X, m_x^{\text{lct}}(m_x) - \varepsilon)$ is log canonical in the sense of de Fernex-Hacon, there exists an integer $m_0 \geq 1$ such that the $m$-th limiting log discrepancy $a_{m,F}(X, m_x^{\text{lct}}(m_x) - \varepsilon)$ is nonnegative for every prime divisor $F$ over $X$ and for every positive multiple $m$ of $m_0$ by [10, Definition 7.1] (see loc. cit. for the definition of the $m$-th limiting log discrepancy of a pair). By the choice of $r$, one has

$$a_{r,F}(X, m_x^{\text{lct}}(m_x) - \varepsilon) = a_{rm,F}(X, m_x^{\text{lct}}(m_x) - \varepsilon) \geq 0.$$ 

It follows from an argument similar to the proof of [10, Proposition 7.2] that there exists an effective $\mathbb{Q}$-divisor on $X$ such that $K_X + \Delta$ is $\mathbb{Q}$-Cartier of index $r$ and $(K_X + \Delta; m_x^{\text{lct}}(m_x) - \varepsilon)$ is log canonical. If $X$ is not quasi-Gorenstein at $x$, then by Proposition 5.9,

$$\text{lct}_x(m_x) < \text{lct}_x(m_x) - \varepsilon + \frac{1}{r} \leq \text{lct}_x(\Delta; m_x) + \frac{1}{r} \leq d_x(m_x).$$

This contradicts the assumption that $\text{lct}_x(m_x) = d_x(m_x)$. □

**Corollary 5.11.** Let $(X, x)$ be a log terminal singularity, in the sense of de Fernex-Hacon, over an algebraically closed field of characteristic zero. Then $\text{lct}_x(m_x) = d_x(m_x)$ if and only if $(X, x)$ is Gorenstein.

**Proof.** Since $(X, x)$ is log terminal, using the minimal model program for klt pairs, one can show that the anti-canonical cover $\bigoplus_{n \geq 0} \mathcal{O}_X(-nK_X)_x$ is Noetherian (see [23, Theorem 92]). Thus, the assertion follows from Theorem 5.10. □

**Proposition 5.12.** Let $R$ be a normal standard graded ring, with $R_0 = k$ a field of characteristic zero, and let $m$ denote the homogeneous maximal ideal of $R$. Suppose that $\text{Spec } R$ has only Du Bois singularities. Then $d(m) \leq -a(R)$.

**Proof.** Put $X = \text{Spec } R$. Since $X$ has only Du Bois singularities, $a(R) \leq 0$ by [26, Theorem 4.4]. Suppose that $\mathcal{I}(\omega_X, m^t) = \omega_X$ with $t > 0$. Let $\varphi: Y \longrightarrow X$ be the blow-up of $X$ at the maximal ideal $m$ and $\widetilde{E} = \text{Proj } R$ be the exceptional divisor. Take a log resolution $\psi: \widetilde{X} \longrightarrow Y$ of $(Y, E)$ and let $\tilde{E}$ be the strict transform of $E$ on $\widetilde{X}$. We fix a canonical divisor $K_{\widetilde{X}}$ on $\widetilde{X}$ such that $\psi^*K_{\widetilde{X}} = K_Y$. Since $\mathcal{I}(\omega_X, m^t) = \omega_X$,

$$\text{ord}_E([K_{\widetilde{X}} + \text{div}_{\widetilde{X}}(f) + \varepsilon \tilde{E} - (t - \varepsilon)\psi^*E]) \geq 0$$

for all $f \in \omega_X$ and all sufficiently small $\varepsilon > 0$. Taking the direct image by $\psi$, we see that $\text{ord}_{\tilde{E}}([K_Y + \text{div}_Y(f) + \varepsilon E - (t - \varepsilon)\tilde{E}]) \geq 0$, that is, $\varphi_*\omega_Y([\varepsilon - t]E) = \omega_X$ for sufficiently
small $\varepsilon > 0$. On the other hand, it is easy to see by the definition of $\varphi$ (see, for example, \cite[Proposition 6.2.1]{21}) that
\[ \varphi_* \omega_Y([\varepsilon - t]E) = [\omega_X]_{[t - \varepsilon] + 1}. \]
Thus, $t \leq -a(R)$, that is, $d(m) \leq -a(R)$. \hfill \Box

As a consequence, we can prove a characteristic zero analogue of Conjecture 1.1, which gives an affirmative answer to \cite[Conjecture 6.9]{11}.

**Corollary 5.13.** Let $R$ be a normal standard graded ring, with $R_0$ an algebraically closed field of characteristic zero. Let $m$ denote the homogeneous maximal ideal of $R$. Assume that $X := \text{Spec } R$ has log canonical singularities in the sense of de Fernex-Hacon.

1. Then $\text{lc}(m) \leq -a(R)$.
2. Suppose in addition that the anti-canonical cover $\bigoplus_{n \geq 0} O_X(-nK_X)$ is Noetherian (this assumption is satisfied, for example, if $X$ has log terminal singularities in the sense of de Fernex-Hacon or if $R$ is $Q$-Gorenstein). Then $\text{lc}(m) = -a(R)$ if and only if $R$ is quasi-Gorenstein.

**Proof.** Since (1) follows from Lemma 5.7 (1) and Proposition 5.12, we will show (2). Let $x \in X$ be the closed point corresponding to $m$. If $\text{lc}(m) = -a(R)$, then $\text{lc}(m)$ has to be equal to $d_x(m)$ by Remark 5.5, Proposition 5.12 and an argument similar to the proof of Proposition 3.9. It follows from Theorem 5.10 that $X$ is quasi-Gorenstein at $x$, which is equivalent to saying that $R$ is quasi-Gorenstein.

Next we will show the “if” part of (2). Suppose that $R$ is quasi-Gorenstein. Let $\varphi : Y \rightarrow X$ be the blow-up of $X = \text{Spec } R$ at the maximal ideal $m$ and $E = \text{Proj } R$ be the exceptional divisor. Note that $Y$ is normal and quasi-Gorenstein. It is easy to see that $K_{Y/X} = -(1 + a(R))E$, see, for example, the proof of \cite[Proposition 5.4]{30}. Take a log resolution $\psi : \widetilde{X} \rightarrow Y$ of $(Y, E)$, and then
\[ K_{\widetilde{X}/X} + a(R)\psi^* E = K_{\widetilde{X}/Y} + \psi^*(K_Y/X + a(R)E) = K_{\widetilde{X}/Y} - \psi^* E. \]

Since $X$ has only log canonical singularities, $E$ has also only log canonical singularities. It follows from inversion of adjunction for log canonical pairs \cite{22} that $(Y, E)$ is log canonical, which implies that all the coefficients of the divisor $K_{\widetilde{X}/Y} - \psi^* E$ are greater than or equal to $-1$. Thus, $(X, m_{\leq a(R)})$ is log canonical, that is, $\text{lc}(m) \geq -a(R)$. \hfill \Box

When the ring is toric, we have a similar characterization in the non-standard graded case:

**Corollary 5.14.** Let the notation be the same as in Corollary 3.18. Let $R = k[\sigma^\vee \cap M]$ be an affine semigroup ring over a field $k$ of characteristic zero, defined by a strongly convex rational polyhedral cone $\sigma$. Let $m$ be the unique monomial maximal ideal of $R$.

1. Then $d(m) = -a(\sigma)$.
2. Suppose in addition that the anti-canonical cover $\bigoplus_{n \geq 0} O_X(-nK_X)$ is Noetherian (this assumption is satisfied, for example, if $X$ has log terminal singularities in the sense of de Fernex-Hacon or if $R$ is $Q$-Gorenstein). Then $\text{lc}(m) = -a(\sigma)$ if and only if $R$ is Gorenstein.

**Proof.** We may assume that $k$ is algebraically closed. Since (2) follows from (1), Remark 5.5, and Corollary 5.11, it remains to justify (1). For this, use the same strategy as the proof of Corollary 3.18, in which case the assertion follows from \cite[Theorem 2]{5} and Lemma 5.7 (1). \hfill \Box
